would represent separate clones. Tc-resistant transformants were selected and screened for resistance to Cm. Over 90% of those clones resistant to Tc were sensitive to Cm, indicating interruption of the continuity of the Cm resistance gene; plasmids from 25 of these were isolated and examined by agarose gel electrophoresis<sup>9</sup> after *Eco*RI cleavage. Twenty of the cloned plasmids were found to contain a single DNA insert approximately 3,300 base pairs in length (Fig. 1); the remaining five plasmids had undergone deletion of vector DNA in the vicinity of the *Eco*RI cleavage site. Using *Bam*HI endonuclease, which cleaves the pACYC184 and HBV DNA molecules asymmetrically, we found that both orientations of HBV DNA insertion were equally represented in these clones (data not shown).

The identity of the DNA insertions within pACYC184 was verified by cleavage of a selected composite plasmid (pHBV1) by several different site-specific endonucleases and by hybridisation of radioactively-labelled HBV DNA to the endonuclease-cleaved recombinant plasmid (Fig. 2). In addition, to facilitate further studies of the structure of the HBV genome and the proteins that it encodes, an endonuclease cleavage map (Fig. 3) of the pHBV1 plasmid was constructed using the procedure of Smith and Birnstein<sup>10</sup>. The location of endonuclease cleavage sites within cloned pHBV1 DNA is in agreement with a preliminary map (Siddiqui *et al.*, in preparation), constructed for HBV DNA isolated directly from Dane particles obtained from the same human carrier. This finding provides further verification of the nature of the DNA insert contained in the pHBV1 plasmid, and indicates also that the entire HBV genome is present and stably maintained in the recombinant plasmid. Experiments reported recently by Fritsch *et al.*<sup>11</sup> indicate that recombinants between HBV DNA and bacteriophage  $\lambda$ gtWES.4B can also be propagated stably in *E. coli* K12.

Landers *et al.*<sup>4</sup> reported that the sum of fragments produced by *Hae*III endonuclease cleavage of Dane particle HBV DNA is greater than the molecular size of the entire virus, and concluded that the DNA molecules contained in different Dane molecules were not identical. In our studies of HBV DNA cloned in *E. coli* K12, we have observed that the sum of the sizes of the *Hae*III fragments in 20 separate clones equals exactly the molecular weight of the virus. The difference between the fragmentation patterns observed by us for *Hae*III-digested cloned HBV DNA, and the pattern reported by Landers *et al.*<sup>4</sup> using Dane particle DNA obtained from a different carrier resides partly in the two largest *Hae*III-generated fragments of the virus; *Hae*III cleavage of the DNA studied by Landers *et al.* yielded a doublet with components estimated to be 986 and 957 base pairs. Electrophoresis of the cloned DNA showed a single fragment having a mobility consistent with a size of 986 base pairs, as did fully-stranded Dane particle DNA isolated from that carrier. Electrophoresis of a mixture of *Hae*III-cleaved pHBV1 DNA with identically digested DNAs from 19 other HBV-pACYC184 recombinant plasmids we have studied showed no double band at the relevant location in the gel.

In addition, the cloned DNA does not show the 750-base pair *Hae*III-generated fragment found in Dane particle DNA by Landers *et al.*<sup>4</sup> Since this fragment appeared only in Dane particle DNA that was elongated with endogenous DNA polymerase in the presence of deoxyribonucleoside triphosphates, its presence may have resulted from incomplete 'fill in' of the single-stranded portion of the HBV genome.

The ability to clone the total genome of HBV in an *E. coli* K12 strain now allows the amplification and propagation of hepatitis viral DNA species isolated from individual carriers and the production of substantial quantities of HBV DNA for further structural studies. Investigation of endonuclease cleavage patterns of cloned Dane particle DNA derived from different carriers showing the same viral subtype, and from individuals infected with different subtypes, should elucidate the extent of heterogeneity of the HBV genome in such carriers and should enable correlation of DNA primary structure with subtype specificity.

In addition, the prospect of expression in bacterial cells of peptides encoded by the cloned HBV viral genome potentially provides a means of synthesising large amounts of viral surface antigen suitable for use in production of a vaccine for viral hepatitis.

These investigations were supported by grants from the NIH, the NSF and the American Cancer Society (ACS) to W.S.R. and S.N.C. J.J.S. is a postdoctoral fellow of the ACS.

## Improved amorphous semiconductors for solar cells

OVSHINSKY AND MADAN<sup>1</sup> have described the interesting results of incorporating fluorine in glow discharge deposited amorphous silicon (in particular a very low density of states within the gap.) However, as one would expect on general grounds, fluorinated material has a significantly larger energy gap than hydrogenated material. It therefore offers an even less good match to the solar spectrum, which would not improve the efficiency of solar cells made from it. Although the use of iodine rather than fluorine might be expected to be helpful in this respect it is still unlikely to reduce the energy gap to the near 1 eV value required for optimum spectral response. [The stability of the Si-I bond shown by the surface stabilisation of silicon by iodine<sup>2</sup>, led me to discuss the possible use of iodine in glow discharge deposited silicon with several workers at the International Conference on the Physics of Semiconductors at Edinburgh in September 1979.]

During our group's early work on glow discharge deposition of amorphous materials (see refs 3, 4) it was observed that germanium and silicon-germanium alloys deposited by glow discharge from germane or germane-silane mixtures, even with rather small germanium content, show negligible photoconductivity compared with pure silicon. This would now be interpreted in terms of the Ge-H bond being weak compared with the Si-H bond, with the result that dangling bonds on germanium atoms are not stably hydrogenated in amorphous germanium and its alloys, and with the further consequence that these materials have a large density of states in the gap. It would therefore not be possible to prepare solar cells from them even though their absorption edge could be well matched to the solar spectrum. Clearly this situation would alter if a stronger bonding element, such as a halogen, were used to satisfy germanium dangling bonds. (Even the Ge-I bond is far more stable than Ge-H). What is suggested, then, is that particularly promising amorphous semiconductors for making efficient solar cells would be germanium and Ge-Si alloys incorporating halogen, the overall composition tailored to optimise the photoconductive response spectrum to solar radiation.

*Note added in proof:* The optimum energy gap for matching a cell to the AM1 solar spectrum is about 1.4 eV (see, for example, ref. 5). However, even at the Equator the Sun is not long at the zenith (implied by AM1), and the increasing atmospheric absorption at lower solar angles characteristic of most of the day (all of it at higher latitudes, outside the tropics) shifts the optimum energy gap to still lower values. It would only be with high temperature operation (above ~300 °C) that fluorinated amorphous silicon could be considered to provide a good spectral match. As the main aim in developing large area solar cells is to avoid concentration of radiation, the maximum temperature likely to be encountered with them is perhaps 65 °C.

C. H. L. GOODMAN

5. Loferski, J. J. *J. appl. Phys.* **27**, 777 (1956).

OVSHINSKY AND MADAN REPLY—Goodman suggests that (1) the optimal energy gap for solar photovoltaic energy conversion is 1 eV and (2) fluorinated amorphous silicon has a significantly larger energy gap than hydrogenated amorphous silicon, and thus concludes that amorphous germanium or Ge-Si alloys are preferential to amorphous silicon for solar-cell applications. Both of the above premises are incorrect.

It is well known<sup>1,2</sup> that the optimal gap for solar photovoltaic energy conversion is about 1.6 eV, not 1 eV. For example, the maximum efficiency for Am-0 using a semiconductor with an energy gap of 1.6 eV is about 25%, more than half again as large as the 16% maximum efficiency of a material with a 1.0 eV gap<sup>3</sup>. Furthermore, the energy gap of our new amorphous Si:F:H alloy is determined by a Fowler plot and clearly stated in our letter<sup>4</sup> is 1.65 eV, which is essentially the optimal value. In fact, it is not significantly different from the energy gaps of 1.55–1.8 eV obtained in silane-decomposed films<sup>5,6</sup>, nor is it much larger than the 1.5 eV gap of nominally pure amorphous silicon<sup>7,8</sup>. The reason for this is that the

fluorine concentration of the new alloy is <5% and thus the vast majority of the chemical bonds that determine the energy gap of the material are ordinary Si-Si covalent bonds.

The major purpose of our letter<sup>4</sup> was to point out that the new alloy has many features in addition to its band gap that makes it more desirable than silane-decomposed material for solar-cell applications.

*Note added in proof:* Goodman in his note in proof now suggests that higher air-mass conditions would greatly deteriorate the performance of amorphous Si:F:H solar cells on the basis of a 1.65-eV gap. The facts are as follows<sup>9</sup>. At AM-2, when the sunlight is at an angle of 60° to the Earth's surface (approximately the spectrum for average, slightly hazy weather conditions and smaller sun angles, as in temperate-zone climates), the maximum conversion efficiency of an ordinary solar cell is ~26%. For a gap of 1.65 eV, the maximum conversion efficiency is still 25%. This figure, in fact, is larger than the maximum conversion efficiency at any energy gap for AM-0 conditions (because of the decrease in relative solar irradiance in the near infrared at AM-2). The main point is that the maximum conversion efficiency is only a weak function of energy gap in the 1.0–2.0 eV range (never dropping below 20% in this range at AM-2), so that the efficiencies of real devices are much more dependent on other parameters.

## Asbestos-enhanced uptake of carcinogens

THE results of Lakowicz and Hylden's studies<sup>1</sup> on asbestos-mediated uptake of benzo(a)pyrene (BP) by dipalmitoyl L- $\alpha$ -phosphatidylcholine (DPPC) vesicles are more indicative of *in vivo* transfer of BP from particulates to lung surfactant (mainly DPPC and other phospholipids<sup>2</sup>)

than transfer of BP from particulates to biological membranes (mainly phospholipids and globular proteins<sup>3</sup>). As a monomolecular layer of surfactant containing DPPC exists at the air-liquid interface in the lung, BP adsorbed onto inhaled particulates would be at least partially transferred to lung surfactant before transfer to cell membranes would be initiated.

I suggest that the reported<sup>1</sup> increased rate of transfer for BP adsorbed to particulate silica or amosite asbestos as compared with BP in a microcrystalline form is principally a result of the adsorption of the mobile DPPC vesicles onto the particulate surface, rather than increased solubilisation of BP in an aqueous phase. It has been shown that DPPC readily adsorbs onto the surface of glass fibres and various types of asbestos, including amosite<sup>4</sup>. The adsorption is controlled by coulombic interactions between the ionic head group of the DPPC and the electrostatic charge of the particulates. The particulate surface charge also is significant in determining particulate-membrane interactions<sup>4</sup>. While the particulate surface charge controls DPPC adsorption, the particulate specific surface area and the form of the adsorbed BP (such as microcrystalline or monomeric<sup>1</sup>) determine the surface area covered with BP at the particulate-liquid interface and thus the availability of BP for transfer to adsorbed DPPC or cell membranes. The interfacial availability of BP would govern relative transfer rates for particulates, such as silica and amosite, which display essentially the same surface charge<sup>4</sup>. On the basis of these comments, I suggest that the preferential interfacial transfer of carcinogens to cell membranes and/or lung surfactant at the particulate surface may be an important factor in co-carcinogenesis.

LAKOWICZ ET AL. REPLY—we are aware that DPPC is a major component of lung surfactant; however, it is not known whether carcinogens which are adsorbed to particles are eluted during contact with surfactant or after subsequent contact with cells. For this reason we are investigating the effects of asbestos and silica on uptake of BP into natural membranes, namely rat liver microsomes and 3T3 cells. Again we find that these particles enhance BP uptake and that asbestos is

more effective than silica. Thus, it is clear that the particle-enhanced uptake of BP is a more general phenomenon which could occur not only in lung surfactant but also in lung cells.

The mechanism of the transfer process has not been elucidated. We suggested that the particle enhancement of uptake results from an increased rate of solubilisation of the BP in the aqueous medium, whereas Light proposes that the transfer of the BP is to vesicles which have become bound to the particulates. The basis for our argument comes from more detailed studies of the particle-enhanced uptake of another polynuclear aromatic hydrocarbon (PAH), 1,2-benzanthracene, into DPPC vesicles<sup>1</sup>. In that instance we measured virtually the same uptake kinetics over a wide range of particle to DPPC ratios. For this reason we propose that the enhanced uptake results from an increased rate of solubilisation of these PAH by virtue of their association with the particulate materials. We do not intend to indicate that the particles can increase the equilibrium solubility of the PAH.

## The evidence for species guilds is an artefact

THE evidence cited by McNaughton<sup>1</sup> that ecosystems are loosely linked sets of species guilds seems to be based on an unfortunate artefact. Although the independent occurrence of species in samples is appropriately tested using the point correlation coefficient ( $V$ ), it is effectively precluded by the sampling method used. This leads to a non-zero expectation for the point correlation coefficient for species whose spatial distributions are independent.

The dependence introduced by the sampling method may be demonstrated analytically. If an area occupied by a number of species distributed independently in space is sampled and the resulting distributions of the  $a$ th and  $b$ th species ( $A$  and  $B$ ) among samples are independent, then

$$P\{A \cap B\} = P\{A\}P\{B\} \quad (1)$$

Where the events  $A$  and  $B$  are the occurrence in a sample of  $A$  and  $B$ , respectively. However, if it is sampled in the manner described by McNaughton it can be shown that

$$P\{A \cap B\} = P\{A\}P\{B\} - (1 + (k-1) \times (h+1) + k^2 g_a g_b) f_a f_b / (g_a g_b) \quad (2)$$

In this,  $f_i$  is the proportionate cover of the  $i$ th species,  $g_i = 1 - f_i$ , and, summing over all species except  $A$  and  $B$ ,  $h = \sum_i f_i$  and  $k = \sum_i f_i / g_i$ . As  $g_i \leq 1$  for all  $i$ ,  $k \geq h$ , so that equation (2) implies

$$P\{A \cap B\} \leq P\{A\}P\{B\} - h^2(1 + g_a g_b) f_a f_b / (g_a g_b)$$

Hence, as long as  $A$  and  $B$  occur, together with at least one other species (that is  $0 < P\{A \cap B\} < 1$ ),

$$P\{A \cap B\} < P\{A\}P\{B\}$$

This contradicts equation (1). It follows that if two species independently distributed in space are sampled by this method and a point correlation can be calculated between them, its expected value is negative.

Due to its dependence on  $k$ , this bias declines with increased numbers of species as long as the form of the species abundance curve remains consistent. To determine the extent to which this might account for the effects observed by McNaughton, the sampling method was simulated on a computer, the first individual of each sample being selected at random from the species complement, the second at random from all species except that of the first. The average interaction term  $i$  and connectance  $c$  were estimated for sets of 100 sample points in the manner used by McNaughton, calculating  $V$  only when both species were represented by at least 10 individuals.

The extent of the bias in  $V$  depends on the frequency distribution of species abundance. It was postulated that the ranked population frequencies of the

Fig. 1 The relationship between average interaction strength and number of species generated by the use of the sampling method of McNaughton<sup>1</sup> on species distributed independently in communities with log-series species abundance curves (solid line) for comparison with that reported for African grasslands.

Fig. 2 The relationship between connectance and species number generated with the sampling method of McNaughton from communities with log-series species abundance curves for species distributed independently in space (solid line) for comparison with that reported for African grasslands.

species sampled formed a geometric series, with common ratio  $\exp(-1/\alpha)$ . Random sampling from such a distribution yields a log-series species abundance curve with diversity index<sup>2</sup>  $\alpha$ . Such curves have frequently been found to provide an adequate description of species abundance data, albeit largely for insects<sup>2</sup>, and have the advantage that they are effectively completely determined by sample size and species number.

Mean values of species number ( $s$ ),  $\hat{c}$  and  $\hat{\alpha}$  were determined for various values of  $\alpha$ . The relations of  $\hat{c}$  and  $\hat{\alpha}$  to  $s$  thus obtained are superimposed on the data of McNaughton in Figs 1 and 2. The curves seem to fit the data points adequately, leaving no residual systematic effect, affirming that the apparent decline in these parameters with increased species number is an artefact of the sampling method used.

## Stability and diversity in grassland communities

In his analysis of the stability properties of large, randomly constructed model ecosystems, May<sup>1</sup> contradicted the existing ecological dogma—that increased community complexity produces increased stability—by showing that in Lotka–Volterra models, dynamic stability is diminished with increases in: (1) the number of species ( $S$ ); (2) the average strength of the interactions among species ( $i$ ); (3) the connectance of the system ( $c$ ), that is, the proportion of non-zero values for  $i$  in the community interaction matrix.

He showed that the system is almost certainly stable if

$$i(Sc)^{1/2} < 1 \quad (1)$$

McNaughton<sup>2</sup> uses data from a study of the interactions among plant species in 17 grassland stands in the Serengeti National Park to test May's results, and concludes that both average strength of interaction and connectance are negatively correlated with species richness, implying that the structure of these grassland communities is constrained in special ways to meet the requirements for local stability. If this were true, it would be an important conclusion<sup>3</sup>. Unfortunately, McNaughton's results are an inevitable consequence of varying  $S$ , and hence say nothing about whether interactions in these communities are constrained by dynamic interactions between species.

McNaughton measures the strength of interaction among the plant species by applying to nearest-neighbour data<sup>4</sup> the point correlation coefficient,  $V$  (giving limits of  $+1$  if the two species always occur

we hope that further analysis of data of this kind will now be attempted by others.

J. H. LAWTON  
S. P. RALLISON

5. Poole, R. W. *An Introduction to Quantitative Ecology*, 336 (McGraw-Hill, New York, 1974).

MCNAUGHTON REPLIES—Lawton and Rallison's statement that "as species richness increases,  $V$  is bound to decrease" is incorrectly applied to my Letter. As I reported negative values for  $V$ , the number of contacts would have increased, not decreased, had my initial report been correct. But it was wrong and Harris accurately identified the flaw.

I am grateful to them for calling attention to my error and hope that other ecologists using  $2 \times 2$  contingency tests in this type of analysis will not make my mistake, whether using  $V$  or other statistics, such as  $\chi^2$ . I should have calculated an expected  $V$ , based on the species' relative abundance, and then used the  $t$ -test based on the  $z$ -transformation to determine whether the calculated  $V$  departed from the expected value. It is, therefore, of value to other ecologists who use nearest-neighbour analysis, or similar methods based on contingency testing, to have the expected values of the cells.

Using the traditional notation of  $a, b, c, d$ , for the cells of the  $2 \times 2$  table, expected values for all sampling events consisting of two consecutive draws with replacement are, if the individuals are randomly arranged,  $a = 2f_x f_y$ ,  $b = f_x^2 + 2f_x h$ ,  $c = f_y^2 + 2f_y h$ , and  $d = h^2$ , where  $f_x = n_x/N$ ,  $f_y = n_y/N$ , and  $h = 1 - f_x - f_y$ .

This obviously results in an expected negative value of  $V$  that increases in magnitude as  $f_x$  and  $f_y$  increase. But it also allows a straightforward test of spatial associations comparing observed and expected values of  $V$ . If, on the other hand, nearest neighbours of the same species are classified as 'pseudospecies', one traditional method in nearest-neighbour analyses,  $f_x^2$  and  $f_y^2$  are removed from the  $b$  and  $c$  cells and added to the  $d$  cell, resulting in expected positive values of  $V$  for randomly distributed individuals.

Another alternative previously used in nearest-neighbour analyses of vegetation is to classify intraspecific nearest neighbours as 'no contacts', eliminating them from the analysis. But then each cell must be corrected by  $1 - f_x^2 - f_y^2 = m$ , which apparently has not been done, and  $a = 2f_x f_y/m$ ,  $b = 2f_x h/m$ ,  $c = 2f_y h/m$ , and  $d = h^2/m$ . Finally, I redrew (selected the next nearest neighbour of another species) when nearest neighbours were members of the same species. To my chagrin, the

## Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

together,  $-1$  if they never do, and a value of  $0$  if the species are distributed independently<sup>5</sup>, and shows that  $V$  is negatively correlated with  $S$ . However, he seems to make no allowance for the fact that, as species richness increases,  $V$  is bound to decrease. Harris presents the argument in full.

Finally, McNaughton<sup>2</sup> draws attention to another theoretical possibility, suggested by May<sup>1</sup>, which also enhances the probability of stability in ecological systems; namely, that communities are organised into blocks of species. McNaughton suggests that the size of these blocks (or guilds) can be estimated by  $Sc$ . Unfortunately,  $Sc$  says nothing about whether the connections between species are 'blocked' and cannot measure the size of these blocks, even if they exist. Blocking depends on the arrangement of the interactions between species, and not on how many there are.

However, we agree with McNaughton that it is important to attempt to test stimulating ecological theories in the field, and

expected value of  $V$  with this approach also is negatively biased with

$$a = 2f_x f_y + f_x^2(f_y/1 - f_x) + f_y^2(f_x/1 - f_y)$$

$$b = 2f_x h + f_x^2(h/1 - f_x) + \sum_{i=1}^s [f_i^2(f_x/1 - f_i)]$$

$$c = 2f_y h + f_y^2(h/1 - f_y) + \sum_{i=1}^s [f_i^2(f_y/1 - f_i)]$$

and

$$d = h^2 - \sum_{i=1}^s [f_i^2(f_x/1 - f_i)] - \sum_{i=1}^s [f_i^2(f_y/1 - f_i)],$$

where  $f_i$  is  $n_i/N$  for each of the  $s$  species other than  $x$  and  $y$ . When I reanalysed my data, using the  $t$ -test as described above, the negative correlations I reported disappeared completely, as Harris predicted.

References 13–15, 18 and 19 in my initial Letter, as well as other sources<sup>2</sup>, can be consulted for abundant evidence justifying my assumption that the spatial arrangements of individuals in local areas may reveal the nature of interactions among them. Naturally, experimentation would be the next step.

I thank W. T. Starmer for taking me 'back to basics', showing me two of the possible ways of treating intraspecific nearest neighbours and pointing me in the direction of others.

## Mutagenic effect of aromatic epoxy resins

ANDERSEN *ET AL.*<sup>1</sup> state that 'the demonstration of a mutagenic effect of aromatic epoxy resins (that is, those based on bisphenol acetone, BPA) indicates a genetic hazard, including a cancer risk, for humans exposed to these compounds'. We challenge the rationale for this rather definite conclusion. Epoxides as a class are reactive chemicals and in general are alkylating agents. However, in the extrapolation from direct alkylation of DNA to defining the risk of mammalian mutagenicity or carcinogenicity, other major factors must be considered, in particular the dose reaching target tissues/molecules and the importance of the detoxication or intoxication mechanisms which are only properly developed in the *in vivo* situation.

Such considerations are being included in a series of mutagenic assays to test for possible mammalian genotoxicity<sup>2–5</sup>. But at present, *in vivo* studies must be con-

sidered as giving more definitive data than work carried out *in vitro* or in non-mammalian systems.

It is surprising, therefore, when a BPA-based epoxy resin which has been tested several times for carcinogenic potential with negative results is now considered to be a potential carcinogen based on the results of a microbial mutagenicity assay (although it does indicate that *in vivo* mutagenicity studies are required). Andersen *et al.*<sup>1</sup> review some of the animal data, but we would summarise the available cancer studies as follows:

(1) Andersen *et al.* do not critically evaluate the paper by Kotin and Falk<sup>6</sup>. The latter do not provide sufficient experimental details, in particular the route and frequency of exposure, to enable any conclusion to be drawn from their work, but it can be stated that there was definitely more than one exposure to the test material.

(2) The results of Weil *et al.*<sup>7</sup> are not correctly interpreted by Andersen *et al.* They carried out two skin painting experiments. In the first, probably 30 mice were used and one papilloma was noted. In a repeat study, probably using 40 mice, no skin tumours occurred. The mortality of these mice was quite normal; there are no grounds for stating that the study was inadequate as the mice were dead in less than 24 months—the mice used by this laboratory lived their normal life span as evidenced by Weil's other data, and an average life span of about 18 months in mice is quite acceptable<sup>8</sup>.

(3) Hine *et al.*<sup>9</sup> carried out a skin painting study, not referred to by Andersen *et al.*, in which a typical BPA-based epoxy resin was tested in both mice and rabbits without any skin tumours developing. Further, reference by Andersen *et al.* to the injection site sarcoma data only must be questioned as these tumours are not generally accepted as providing any reasonable indication of carcinogenic hazard (for example, gold and hypertonic saline were shown to be carcinogenic by this route<sup>10,11</sup>).

In conclusion, the preponderance of available evidence indicates that currently used BPA-based resins present no carcinogenic hazard to man. This assessment is not changed by the evidence of Andersen *et al.*, although their findings should definitely stimulate further mutagenic studies.

ANDERSEN *ET AL.* REPLY—Granville challenges our conclusions based on positive Ames tests with aromatic epoxy resins (AER). He claims that our conclusions are too definite and argues that tests in mammals would much better predict the risk for mutagenic and carcinogenic activity in humans. Conventional animal tests use only about 200 animals and are, therefore, rather insensitive. Only strong carcinogens will be identified by such tests<sup>1,2</sup>.

The animal tests that were made on AER in the 1950s and early 1960s are inconclusive. The tests which did not show tumours are faulty and insufficient. In several cases, exact information on the experimental details is lacking. Only about 100 mice and 50 rabbits were used<sup>3,4</sup>. The rabbit experiment was, according to the authors themselves, rather insensitive. Nevertheless, Granville claims that the experiments indicate that AER does not represent a cancer hazard, despite the experiment—albeit another one suffering from deficiencies in the description of the test conditions—in which tumours were produced by the resins<sup>5</sup>.

Thus our strong suspicions of dangerous effects of AER are in no way disproved by existing animal tests, nor will any new animal carcinogenicity test be able to give definite proof for non-carcinogenicity. It is our opinion that the doubt which might exist about the mutagenic or carcinogenic activity of a chemical substance should be used for the benefit of people who will come in contact with the substance. The only clear proof that AER is not dangerous to humans could come from experiments proving that AER cannot reach the relevant target molecules, namely DNA. As long as these experiments have not been made, AERs must be considered as mutagens and carcinogens.

## Animal Marking

### Recognition Marking of Animals in Research

Edited by BERNARD STONEHOUSE

- \* The edited proceedings of a symposium sponsored by the R.S.P.C.A.
- \* Includes the most up-to-date methods covering a wide range of animals from Molluscs to Elephants.
- \* The concern of the 27 contributors is to promote sensible, practical and above all humane methods of marking.
- \* Royalties from this volume are dedicated to the R.S.P.C.A.

Dec. 1978, £10.00, 0 333 23584 3

# Help

Our technical services group gets calls all the time from researchers who have found that iodinating proteins can be tricky. We usually

have the answers, because at NEN we iodinate proteins ourselves—with our own iodine-125.

Of course, having trouble-free iodine-125 at the outset eliminates some of the trickiness. Ours is the world's most carefully prepared and tested iodine-125.

Each biweekly batch must pass strict tests for radiochemical purity and exact base strength, as well as labeling efficiency in a sensitive lactoperoxidase iodination.

And now the news: We've added a medium concentration, low pH iodine-125. Now you can order any combination of concentration and pH from NEN:

NEZ-033 Standard package  
in 0.1-0.5ml  
of ~0.1M NaOH solution

NEZ-033H High concentration  
>350mCi/ml  
in ~0.1M NaOH solution

NEZ-033L Low pH 8-10  
High concentration  
>350mCi/ml  
in aqueous solution

NEZ-033A Low pH 8-10  
Medium concentration  
100mCi/ml  
in aqueous solution

Send for our Iodine-125 products brochure.  
It tells the whole story.

## Encyclopaedia of Antibiotics 2nd Ed.

by J.S. Glasby, ICI (Organics) Limited, Blackley, Manchester.

The second edition of the encyclopaedia has been updated to include over 400 new antibiotics discovered since the first volume was published. In addition, a number of the structures of these important compounds have been revised in the light of more recent investigations, particularly into their stereochemistry. The form of the encyclopaedia has been retained, listing for each antibiotic the formula, structure, melting point, elaborating organism, methods of preparation and purification, those organisms against which the antibiotic is effective, and toxicity, where these properties are known.

## Table of Isotopes 7th Ed.

edited by C.M. Lederer and Virginia S. Shirley, both of Lawrence Berkeley Laboratory, University of California, Berkeley.

An up-to-date, concise, and readily usable compilation of nuclear data for each mass number, presenting properties of the more than 2600 known isotopes, both stable and radioactive. It includes isotopic mass, natural abundance, nuclear spin, neutron capture and fission cross sections, decay modes and branchings, decay energies, half-life, certainty and means of identification, means of production, energies and intensities of all radiations, angular and polarization correlations of radiations, half-lives of excited states, and level schemes for each nucleus as determined from radioactive decay and from nuclear reactions.

## Mechanisms of Immunopathology

edited by S. Cohen and P.A. Ward, both of the University of Connecticut Health Centre, and R.T. McCluskey, Massachusetts General Hospital.

A comprehensive monograph on how the immune and inflammatory systems interact in disease and in the response to disease. It offers up-to-date coverage of basic principles, immunologic injury, protective aspects of immune responses, and immunologic deficiencies, as well as a discussion of principles of transplantation immunity. The book features contributions from twenty-seven specialists in their fields and a number of experimental models and human diseases as examples in discussing basic principles and mechanisms. ## The Chemistry of Antitumor Antibiotics Volume 1

by W.A. Remers, University of Arizona, Tucson.

A comprehensive coverage of all aspects of the chemistry and biochemistry of antitumor antibiotics and their biology. It emphasizes the development of the intellectual framework of research in this field and provides new insights into the five families of antitumor antibiotics from which at least one established member has been approved for cancer chemotherapy in the US.

## Sensory Mechanisms of the Spinal Cord

by W.D. Willis and R.E. Coggeshall, both of the Marine Biomedical Institute, University of Texas Medical Branch, Galveston.

An up-to-date review of spinal cord mechanisms for sensory processing. After an historical introduction, the chapters review the organisation of the peripheral nervous system from the standpoint of sensory receptors and primary afferent axons; discuss what is known of the structure of the dorsal horn and the activity of dorsal horn interneurons; describe the clinical, behavioural and neuro-physiological evidence for sensory pathways in the white matter of the cord; and deal with the pathways in the dorsal columns, the dorsolateral fasciculus and the ventral quadrant. The final chapter summarises knowledge concerning the receptors and the spinal cord pathways responsible for the sensations of touch-pressure, flutter-vibration, pain, temperature, position sense and visceral sensation.

## R.A. Fisher: The Life of a Scientist

by Joan Fisher Box.

A biography of a man whose achievements in mathematical statistics continue to dominate the age. This synthesises his personal and professional life, tracing the development (without mathematical elaboration) of some of his main contributions to statistical method and scientific inference. It shows how he mobilised and extended the resources of mathematics to solve the problems of estimation, analysis and design of experiments, and inductive inference.

"This is indeed a fascinating book... offers an account, at once informative and human, of a great scientist who gave us statistics as we now know it, while at the same time establishing himself among the great leaders of genetics especially in the study of natural selection and its impact on populations and their properties."

Kenneth Mather, Honorary Professor of Genetics at the University of Birmingham, UK, for NATURE

## Exciting endocrinology

J. A. Parsons

*Pioneers in Neuroendocrinology*, Vol. II. Edited by J. Meites, B. T. Donovan and S. M. McCann. (Plenum: New York and London, 1978.) £20.48.

THIS fascinating collection of micro-autobiographies will delight those who already know that scientists as a group are neither more nor less often inspired, neither more perfect nor more perverse than others who make a living by their wits. It will also be received with joy by those who doubt the second of both these pairs of propositions. There is enough in it to reinforce almost any prejudice and material for many an after-dinner story.

Two quotations may whet the appetite and show the potential of the book in arguments for or against the 'Two Culture' hypothesis.

"Harmony in science respects the same type of stringent rules that can be found in Bach's polyphony . . . It really does not matter, for the progress of science, whether you are personally exploiting one of your previous findings and working on the next discovery, or whether the next step is taken by others who have picked up your idea. Some people feel this is stealing from you. In my opinion, it is the best compliment one scientist can pay another".

"My one application to Jefferson Medical College was rejected, to my parents' chagrin but to my delight, and for the next two years I worked as a professional musician in the Philadelphia area".

Inevitably in a book of this type, the contrast of personal philosophies is as remarkable as the difference in literary styles, but most contributions are penetratingly self-critical and many are full of humour.

"Du Vigneaud once told me that in the isolation of oxytocin, the most efficient purification step had been that of separating the pituitary from the cow".

Also, at a time when the number of young people of exceptional ability who choose scientific research as a career seems to be falling, one value of such a collection of honest attempts 'to tell it like it is' may be to provide an insight into the challenges and rewards of this way of life, far more vivid than any description from a careers officer.

Contributions to this volume were of course only invited from those whose work has succeeded, in the sense of making important contributions to a

relatively new branch of endocrinology. Another way in which its publication can be of general value is therefore by allowing some comparison of research careers and of the contributions made by different types of funding.

As one would expect in our era, the overwhelming majority of the work has received state support. The total of 24 contributors is not a large statistical sample, but it is noteworthy that 20 worked with grants in a university environment. Of the remainder, two were on the staffs of privately endowed research institutes (though they, too, received much state funding), two carried out some of their work in government research institutes, and one was supported principally by the US Veterans Administration.

As it can be predicted with some confidence that during the next decade neuroendocrinology will make major contributions to drug treatment of disease, it is again of some interest that 14 of the contributors had their formal training in physiology and/or anatomy, four in zoology, two in psychology and only two in pharmacology. Only five mention industrial support for some of their work. No less than 12 of the authors were trained as physicians before specialising in a basic science, a career pattern which has now become very rare in the UK.

The editors evidently had no distaste for controversy and several spectacular old battles receive an airing, with much detail of intellectual arguments and strategy and at least one allegation of foul play. The history of science in the making is clearly fraught with the same problems as those encountered in histories of the more distant past. As usual, the details of such accounts are of greatest interest to the participants and those responsible for funding them, but it seems worth drawing attention to one issue of general significance.

Major scientific journals exercise great power, and the forces of competition tend to ensure that their editors exercise this responsibly in maintaining the quality of work accepted. However, an incident which is discussed at some length raises the question whether editors are equally conscious of the responsibility incurred in rejecting a paper. Many will agree that the regret-

table practice of anonymous rejection by the use of a supply of forms is too common; justice and the public interest seem to require that dismissal of any carefully presented paper should be based on equally serious scientific assessment. Not only may ill-considered rejection delay general awareness of work later recognised as important, perhaps by several years if authors are diffident; as illustrated by the incident discussed, still worse may ensue if the rejection is based on comments of a single carelessly-chosen reviewer, who has thus received privileged communication of the results (most dangerous of all if he is a competitor). Justice is usually done in the end—but at what cost?

Quite apart from the human interest, the book is worth reading for its excellent science. For example, there are some of the clearest discussions one could wish of the (unfinished) list of frustrations encountered in trying to isolate the Corticotrophin Releasing Factor. There are also valuable insights into the role of the hypophysial portal circulation, presented notably by Bogdanove and Halász. Incidentally, although its relevance is not directly discussed, this evidence for highly directional transfer rather than simple diffusion of hypothalamic factors should surely lead to an armistice in the old battle over functional significance of the portal vessels. (The argument is here pursued unrelentingly by Lord Zuckerman himself, while Harris' perceptions are ably defended by Dr Donovan.)

In short, the editors are much to be congratulated for their enterprise and for showing clearly how much further excitement neuroendocrinology is likely to provide in the coming years. Perhaps we can look forward to another volume when such important issues are resolved as the structures of CRF, GRF and MIF, the role of prolactin in the origin and development of mammary tumours (interestingly discussed by Meites), and the probable physiological role of centrally acting peptides affecting memory and behaviour (excellently reviewed by de Wied). □

*J. A. Parsons is Head of the Laboratory for Endocrine Physiology and Pharmacology at the National Institute for Medical Research, London, UK.*

## Planetary atmospheres

*Theory of Planetary Atmospheres: An Introduction to their Physics and Chemistry.* By J. W. Chamberlain. Pp. 330. (Academic: New York, San Francisco and London, 1978.) £19.15.

It is a brave person who considers writing a textbook on planetary atmospheres at this time when there are so many space missions to the planets rapidly advancing our knowledge of these bodies. One procedure is to concentrate on basic processes and then use the current planetary observations to illustrate the mechanisms involved. Basically, this is the approach adopted by Professor Chamberlain whose valuable textbook is primarily concerned with the physical and chemical properties of planetary atmospheres. The author has made good of our effluent society, which in the past few years has produced detailed investigations of photochemical processes related to the potential climatic impact of variations in the Earth's ozone layers. This has allowed the discussions to be placed on a moderately firm foundation before their application to the planets.

The book covers approximately 300 pages of text supplemented by some useful appendices. Each of the seven chapters has a valuable list of references, that may be used to extract more detailed analyses of the work presented. In addition, there are problems at the end of chapters that make the text useful as a teaching aid for the rapidly increasing number of courses in planetary studies at universities throughout the world.

The introductory chapter discusses the basic physical concepts and provides the reader with a good background to the vertical structure of the Earth's atmosphere, together with an indication of the differences of structures of the other planetary atmospheres. I thought that the comments on p40 regarding the initial interpretation of the Pioneer 10/11 results for the structure of the upper atmosphere were unnecessary. The problem first identified when reducing these measurements has been resolved. Furthermore, the Voyager observations had now added further important information that indicates interesting structure in the upper Jovian atmosphere which now means that part of Figure 1.19 is out of date. I had hoped that Professor Chamberlain would not have introduced the term "dust" on p38 when discussing the ultraviolet absorbing layer created from photochemical products thought to reside above the visible clouds. This is an unfortunate term, misused for too long.

The introduction to atmospheric motions is well presented, although some aspects of the planetary examples are a little sketchy. In particular the reader still would have no idea why Jupiter (and Saturn too) have cloud bands from the discussions presented here. With many aspects of the Jovian dynamics still to be resolved, it would probably have been better to have shown how spacecraft measurements that could help resolve the controversial issues that currently exist.

The next two chapters are concerned with the chemistry and dynamics of the Earth's stratosphere and planetary astronomy where the basic concepts of radiative transfer are discussed. Professor Chamberlain is well known for his work in these areas, and the work is well presented. I still maintain, from a personal viewpoint, that the classical Chandrasekhar approach to radiative transfer is not the easiest way to introduce the subject to the reader. How-

ever, the references at the end of the chapter contain papers with other approaches, so the reader can decide this matter for himself.

The remaining chapters are concerned with ionospheres, airglows and aeronomy and the stability of planetary atmospheres. This indicates the breath of the discussions which with a good mathematical description form the basis of a useful book. I personally consider this volume a valuable addition to the subject. I sincerely hope, therefore, that the publishers will have the wisdom to produce an inexpensive paperback version so that students attending courses in this rapidly growing subject will be able to purchase a copy of their own.

Garry E. Hunt

*Garry E. Hunt is Head of the Laboratory for Planetary Atmospheres, Department of Physics and Astronomy, University College, London, UK.*

## Guide for Darwin scholars

*Charles Darwin: A Companion.* By R. B. Freeman. Pp. 309. (Dawson: Folkestone, UK; Archon Books/Shoe String Press: Hamden, Connecticut, 1979.) £12.50; \$27.50.

RICHARD FREEMAN is rightly held in high regard for his meticulous labours on the bibliography of Charles Darwin's writings. His equally significant work *Charles Darwin: A Companion* is likely to prove indispensable to Darwin scholars. Interest in Darwin continues to grow, as continued exposure on the media attests and the steady flow of learned publications sustains. Recent discoveries are deftly and economically incorporated with notable conciseness.

There is a clear need for an enumeration of securely determined facts about Darwin: about his family from the sixteenth century record in Lincolnshire to his grandchildren; about the servants, dogs and horses as well as those of their close friends; about the names and ever baffling nicknames of their ramifying and closely intermarrying relatives; and about the Hookers, Huxleys, Henslows and Wedgwoods.

The *Companion* is an alphabetical list of names; wives are listed under their maiden name with a cross reference to their husband. All cross-references are cunningly devised to encourage wandering as should always be the case in a good work of reference. Quotations from Darwin enliven the identity and relevance of each name so that the book becomes a truly

fascinating anthology of quotations as well as a detailed guide to the formidable bibliography. The forty-one pages of material devoted to Charles Darwin required 25 sub-headings listed on page 71. The sub-headings are set in an insufficiently bold type and it would have been helpful to the reader to carry the sub-heading at the top of the relevant page. Particularly worthy of note are the "few quotations to give indications of CD's character" (pages 71-2) which include new discoveries amongst old friends. In his introduction Freeman quotes Darwin's letter to Huxley from Ilkley in November 1859 (LLii281): "The difficulty is to know what to trust." when making a compilation from various sources. Richard Freeman, an accurate compiler with a discerning eye for the unusual, is sadly let down by careless transcriptions in the printed texts. Both Francis Darwin and his sister Henrietta placed unjustified faith in the transcriptions they published. Hence, we read instead of Moscheles as teacher of pianoforte to their mother the name Maschelas, and Henrietta transcribes the name of Darwin's amanuensis and companion Syms Covington as Conington (Emma Darwin ii 19). It was a more recent misreading by a dealer in manuscript letters which resulted in the entry on page 167 for Hoskins an untraceable botanist. The original of this letter to Henslow has since come to light and reveals that CD wrote Hooker, indeed a botanist and in 1845 an unsuccessful candidate for the Chair of Botany at Edinburgh.

Sydney Smith

*Sydney Smith is Emeritus Fellow of St Catharine's College, Cambridge, UK.*

## Theory of conditioning

*Classical Conditioning and Operant Conditioning: A Response Pattern Analysis.* By W. W. Henton and I. H. Iversen. Pp. 355. (Springer: New York, Heidelberg and Berlin, 1978.) DM 54; \$29.70.

THE argument of this book is that the phenomena of conditioning can best be understood by observing behaviour in all possible detail, and describing the effects of contingencies between stimuli, rewards and responses on everything the subject is doing. The authors build up an impressive, if partisan, case for this "response pattern" theory and for the "multiple response" experimental technique which it implies. Along with these latter, however, they bring us a metatheoretical commitment to a hard-line Skinnerism, according to which even the editorial policy of the *Journal of the Experimental Analysis of Behavior* is dangerously revisionist. Any attempt to use behaviour as an index of an underlying state, physiological or mental, is consistently condemned as "phrenology".

This package of experimental method, theory and ideology is applied to five problems: classical conditioning against an instrumental baseline (conditioned suppression and its variants); concurrent operant performances; multiple schedules of reinforcement; collateral (adjunctive) behaviours; and concurrent classical conditioning. In each area the authors produce original experimental ideas and have provocative remarks to make about currently dominant theories, and they repeatedly show that if the attempt is made to record all an animal's behaviour, regularities of response sequencing can be found to underlie effects of reinforcement schedules that have mainly been analysed at a more molar level in the past.

Although Henton and Iversen break away from recording a single "arbitrary operant" response, they still use arbitrary subjects (rat, pigeon, monkey) in wholly artificial, stereotyped learning situations. But it is a little unfair to criticise them for faults they share with most of operant psychology. More seriously, they entirely ignore the regulatory aspect of instrumental responding, which must constrain the subject towards that "averaging over minutes, hours or days" which the authors condemn. In fact they never ask themselves either what the behaviour they observe so microscopically, or the conditioning they are trying to explain, might be for. I cannot help feeling that this blindspot, which greatly weakens

the authors' argument, is partly due to their ideological position.

Minor niggles include the lack of an author index (exacerbated by having separate bibliographies for each chapter), a high misprint rate, a slightly petulant tone savouring of "Reply to Reviewer B" in places, and occasional lapses from English idiom, which, though never a threat to understanding and also forgivable from Iversen, ought to have been caught by his publisher or co-author. There are two serious omissions from the point of view of the reader's convenience. First, the authors miss the opportunity to establish a consistent way of presenting multiresponse data. No book containing detailed accounts of 31 experiments can make easy reading, but repeated changes in

diagram conventions make things harder than they need be. Secondly, we could have done with summary tables, for each chapter or the book as a whole, giving the main procedures and results of all the experiments. As it is, there isn't even a concluding chapter to review and summarise the argument. Nevertheless, the book deserves a welcome, partly for giving an integrated account of an extended research programme, but mainly as an empirical challenge to some widespread current generalisations about conditioning.

## Sensory integration

*Handbook of Behavioral Neurobiology.* Vol. 1: Sensory Integration. Edited by R. B. Masterton. Pp. 579. (Plenum: New York and London, 1978.) £24.88.

IN the words of the publisher *The Handbook of Behavioral Neurobiology* will provide "a critical systematic enquiry into those aspects of neuroscience having the most direct and immediate bearing on overt behaviour." The targets for this first volume are "practising neuroscientists looking for a concise and authoritative treatment of developments outside their particular specialisation, and students who need an overview of the persistent and current problems surrounding the relation of the perceptual systems to behaviour". The eighteen authors were asked to "sacrifice comprehensiveness for illumination". Without exception they have complied with editorial pressure and in so doing have produced a surprisingly well integrated book which should achieve its aims.

The ten chapters dealing with the individual sensory systems form the core of the book. Not surprisingly the visual system claims more space than any of the others, but it is closely followed by the vestibular and auditory systems. Olfaction, in some ways the most interesting of the senses, brings up the rear with less than half the space earned by the gustatory and somatosensory systems. The reader, be he a practising neuroscientist or a student, will probably first turn to one of these chapters; and he will not be disappointed. Without exception the authors have provided illumination and not always at the expense of comprehensiveness.

It would be a pity, however, if the first three integrating chapters escaped attention. Erickson who writes chapter three prefaces it with a quotation from Poincaré: "Science is built up with facts as a house is with stones. But a collection of facts is no more a science than a heap of stones is a house". These first three chapters provide the reader with plans for a house. Erickson himself argues that our knowledge of sensory processes will be constrained "if we resist seeing beyond the idiosyncracies of each system". He then moves towards a general theory of sensory neural function. In the second chapter, Cunningham and Murphy explore the ontogeny of sensory systems and ask whether their developing structure and function are wholly genetically determined. Despite the weight of the present evidence they think not, and predict that future work using anatomical and physiological techniques which can detect the subtleties of sensory perception will show that the contribution of nurture to sensory development is the rule rather than the exception.

Finally the editor's opening chapter surveys the evolutionary history of the six sensory systems. For each he provides a useful common plan for all vertebrates and then briefly discusses any striking variations. He concludes each section with a discussion of the notable changes which have probably occurred in the evolution of the human sensory system in question.

These three chapters provide a good introduction to a useful book which sets a high standard for those which are to follow.

## Vertebrate ovary

*The Vertebrate Ovary: Comparative Biology and Evolution.* Edited by R. E. Jones. Pp. 853. (Plenum: New York and London, 1978.) £43.78.

PUBLICATION of another volume (over 800 pages) on the ovary highlights the expansion of research in this aspect of reproductive biology. Consisting of 24 reviews by leading scientists predominantly from the USA the work is mostly comparative in nature. This is exemplified at the beginning and end of the book by chapters on the origin and segregation of primordial germ cells, in which the anuran germ line receives special attention, and on the evolution of the vertebrate ovary. Morphological differentiation of the ovary is also considered from a comparative viewpoint, but biochemical and genetic factors that influence gonadal differentiation are treated only briefly.

The follicle is reviewed extensively: its genesis, morphology and endocrine function; the hormonal control of its growth and maturation; and the production of follicular fluid. The non-atretic follicle is seen as developing in a predominantly oestrogenic micro-environment that influences follicular growth; processes that result in atresia, and the repercussion of this phenomenon on ovarian function, are examined separately.

Understandably, formation of oogonia, maturation of the oocyte and ovulation receive much attention. Most contributors dealing with mechanistic aspects of ovarian physiology summarise their ideas in the form of hypothesis. This is seen in the description of ovulation, and of oocyte maturation in amphibians, in which the elaborate biochemical events induced by steroids that lead to the formation of the meiotic spindle are examined. Work on this latter aspect contrasts with experiments in mammals which have focused rather on the maturation-inducing action of luteinising hormone and on how the resumption of meiosis is prevented by granulosa cells and follicular fluid inhibitor.

Compared with its close contemporary, *The Ovary* (edited by Lord Zuckerman and B. J. Weir; second edition; Academic: London and New York; three volumes; total price £77.70), it is inevitable that this new book contains chapters on similar topics. However, interpretations by different experts frequently result in essays that are complementary rather than merely repetitious. Valuable additions include reviews of ovarian vasculature, with a description of techniques of blood flow measurement and of the effect of

humoral agents, ovarian innervation, and the fascinating fields of follicular selection and vertebrate fecundity. Discussion of the fate of the ruptured follicle is less satisfactory, as reference to the evolutionary significance of the corpus luteum and the comparative aspects of its structure and function are found dispersed among several reviews. The lack of chapters on ovarian pathology and the influence of external factors on ovarian function is attributed to the restrictions of space, but for a book of this quality the reproduction of photomicrographs deserves a better standard.

A selected sentence from a paper

by Bern (1972) reflects the editor's bias: "we comparative biologists have an aim—the aim to reconstruct from extant species a picture of the evolution of the system in which we are interested". The picture proves complex, frequently displaying diversity rather than conformity. Nonetheless the book should prove valuable for the research scientist, clinician and teacher; and the nature of unanswered questions should stimulate enquiry.

## Climatic impact on organic evolution

*Climate and Evolution.* By Ronald Pearson. Pp. 274. (Academic: London, New York and San Francisco, 1979.) £14.

THIS is an ambitious work that must be taken seriously by anyone interested in palaeoclimatology and biostratigraphy. Such a study, in order to fulfil its title, requires a multi-disciplinary approach to a vast literature and is more than an ordinary mortal could achieve. Pearson, however, is mortal enough, so it is worth seeing where he succeeds and where the book falls short.

The book is organised so that chapters 1–5 are general and 6–11 historical. The introduction concerns evolution only and is brief but to the point. Chapters 2, "A brief history of historical climatology", and 3, "More recent knowledge of climatic change", review the principal hypotheses for climatic change but primarily for changes evident in Quaternary history. This is to some extent balanced by chapter 5, "Long term considerations", with chapter 4, "Geomagnetic considerations", thrown in for good measure. The result is a very brief resume of the mechanisms for climatic change abstracted from many leading authorities in these fields. The remaining chapters are chronological: (6) Palaeozoic; (7) Mesozoic; (8) Tertiary; (9) Quaternary; (10) Late Weichselian and Flandrian; and (11) Climate and [human] history. A consolidated list of more than 750 references and a fairly good index, complete the book.

The author's own viewpoint is evident in the balance of the work. His own publications listed concern Quaternary Coleoptera; and the whole discus-

sion is Quaternary-orientated, so that earlier and possibly more radical climatic and evolutionary changes are increasingly obscured through the mists of time. Precambrian history is accorded token mention and the first metazoan (Ediacaran) fauna (surely of prime significance in such a study) receives only a passing reference without definite mention. In the same chapter discussion of climatic change on the megascale is minimal. For example, the role of atmospheric CO<sub>2</sub> is hardly discussed and the possibility of the first half of the Earth's history being climatically hotter than later because of this and other factors, is not considered. Inevitably too, the consideration of Pre-Quaternary history depends on more stratigraphical knowledge than is easy to acquire for the purposes of such a work.

An alternative approach might have been more satisfactory, namely, to review organic evolution and first identify the developments that need explanation and then to compare climatic and other mechanisms in each case against a critical assessment of the chronological precision of the data brought to bear. And here is a difficulty: inevitably the many chronometric age estimates quoted tend to be taken at their numerical face value, and it would require much research to do otherwise.

In conclusion, this work, except for parts of the Quaternary record, does not provide a critical assessment of the climatic impact on organic evolution but it does a most valuable service in bringing together and abstracting a variety of relevant literature and the wide range of ideas necessary as a preliminary. Most specialists will find something here to challenge their thinking.

## Marine Production Mechanisms

Edited by **M. J. DUNBAR**

Effective control and conservation of food resources in the oceans of the world can only be achieved if the basic mechanisms which control the abundance, distribution and production of marine organisms are fully understood. This volume describes basic productivity studies and studies of ecosystem structure and trophic relations, carried out and presented by experts in various parts of the world. It will be a valuable source of reference for all those engaged in marine research in countries with exploitable marine resources.

## A Perspective of Environmental Pollution

**M. W. HOLDGATE**

The subject of environmental pollution has aroused a great deal of interest and concern in recent years. This book is an attempt to give a balanced view of the effects of environmental pollution and to consider the factors that need to be taken into account when reviewing pollution control. The author concludes that pollution need not be a threat to the future of mankind, but that its prevention will be increasingly important nationally and internationally as the world population increases. A valuable book for students and professionals alike.

## Radicals

**D. C. NONHEBEL, J. M. TEDDER and J. C. WALTON**

The aim of this book is to give students a concise introduction to the chemistry of radicals, an important, but somewhat neglected branch of organic chemistry. The fundamental concepts of radical chemistry are discussed together with the principal types of reaction involving radicals. Emphasis is given to the role of radicals in organics synthesis. This textbook will interest students, research workers in chemistry and biochemistry, food scientists and industrial chemists.

## The Post-Darwinian Controversies

**JAMES R. MOORE**

Victorian controversies between science and religion have been the subject of many scholarly studies, but no book has hitherto appeared which offers such an original interpretation of Protestant responses to Darwin after 1870, viewing them in a transatlantic perspective and as a constitutive part of the history of post-Darwinian evolutionary thought. The detailed and scholarly treatment of this interesting topic will be invaluable to historians of science and theology and to social historians.

## What Little I Remember

**OTTO FRISCH**

In this delightful autobiography Otto Frisch relates some of the most exciting developments of modern physics, including the discovery of nuclear fission, a term he himself coined. His vivid description of those heady days which saw the birth of radioastronomy, the unravelling of the double helix and the making of the first atomic bomb creates the background for his pen portraits, enlivened by

entertaining anecdotes, of the many great scientists he has met. His lively account will be enjoyed by everyone, scientists and general readers alike, with an interest in the history of modern physics.

## Microbial Technology

Current State, Future Prospects

Edited by **A. T. BULL, D. C. ELLWOOD and C. RATLEDGE**

This volume provides both an up-to-date account of the current state of microbial technology and an indication of future research prospects in this subject of growing industrial importance. The relevance of microbial technology will become increasingly apparent as traditional raw materials and energy sources become depleted. This book illustrates the interdisciplinary nature of microbial technology and refers to relevant developments in related areas which combine to make it an exciting prospect for the future and a field of tremendous industrial potential.

## A new approach in tissue culture

**PETRIPERM**  
a novel culture dish  
with gas permeable  
membrane as cellular  
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
  - Suitable for high power light and fluorescence microscopy
  - The membrane can be cut for cell cloning, electron microscopy, staining and documentation
  - Chemically resistant to acids, bases and organic solvents
- PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO<sub>2</sub> of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO<sub>2</sub>, pCO<sub>2</sub> and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

# obituary

## Sir Edward Salisbury

SIR EDWARD JAMES SALISBURY, CBE, FRS, who died on 10 November 1978 at the age of 92, was one of the best known British botanists of his generation.

He was born on 16 April 1886 at Limbrick Hall, Hertfordshire, his father, J. Wright Salisbury, being a member of a distinguished family long resident in the area. He was educated at University College School and then at University College, London, which he entered as an undergraduate in 1905, graduating with an honours degree in botany in 1908. He stayed on as a research student, from 1910 onwards as Quain Student; moved to East London College in 1914 as senior lecturer in botany, and returned to University College as lecturer in 1918. In 1924 he was made university reader in plant ecology, and succeeded F. W. Oliver as Quain Professor in 1929, retaining this post until he was appointed director of the Royal Botanic Gardens, Kew, in 1943. He retired from the directorship in 1956 at the age of 70. He was elected Fellow of the Royal Society in 1933, was awarded its Royal Medal in 1945, and served as Biological Secretary from 1945 until 1955. He was made CBE in 1939 and was knighted in 1946.

Salisbury showed an interest in plants at quite an early age. By his 15th birthday, when one of his presents was a copy of Hooker's *Student's Flora*, he had a garden plot in which wild plants he had collected were labelled with their Latin names, had formed a private herbarium and could identify most of the flowering plants of Hertfordshire. He went to University College during an important period of change in attitude towards the scientific study of plants.

The professor of botany was F. W. Oliver, and A. G. Tansley was a lecturer on his staff from 1893 until his return to Cambridge in 1907. Both had been much influenced in their research and teaching by the striking advances in palaeobotany of the few previous decades. Just before the turn of the century, however, Oliver embarked on his studies of coastal vegetation and Tansley became deeply interested in the 'ecological' and physiological aspects of plant geography as expounded by Warming and Schimper respectively. They had been increasingly dissatis-

fied with the almost exclusive attention to comparative morphology and anatomy which still characterized much botanical teaching and welcomed the ecological emphasis on the plant as a functional whole.

Salisbury was immediately attracted by Oliver's lectures and especially by his field excursions to the north Norfolk coast and elsewhere. After graduation he elected to work with Oliver and two joint papers appeared in 1913, one being a lengthy general account of the ecology of Blakeney Point. Meanwhile his ecological interests were extending to problems of inland vegetation and especially of woodlands, and his now classic studies of variations in the woodland light climate with season and with stage in the coppice-cycle, and their effects on the ground flora, soon attracted attention. He was already laying the foundations of his reputation as a leading academic botanist, and his appointment to the Quain Chair in 1924 greatly increased his influence.

This was early exerted through the series of text-books written in collaboration with F. E. Fritsch. *An Introduction to the Study of Plants* was published in 1914 by G. Bell & Sons and was immediately successful in encouraging the consideration of plants as living and functioning wholes rather than as assemblages of organs, tissues and cells. The last of the famous 'Fritsch & Salisbury' series was *Plant Form and Function* (1938).

While still a research student Salisbury was invited to join the British Vegetation Committee, set up in 1904 to coordinate current work on the survey and study of British vegetation and converted in 1913 into the British Ecological Society. Salisbury was a founder member of the Society and was invited to join its council and to become hon. secretary in 1915, an office he held until 1931. He was elected president for the two years 1929-30.

His presidential address, 'The biological equipment of species in relation to competition' (1929), reveals very clearly how far British ecology, with its primary aim of understanding why plants of some species but not of others grow in a given area, had come to differ from continental ecology with its largely floristic interest and its emphasis on the description and classification of plant communities. Certainly Salisbury was relatively little interested in plant communities as such. His main

concern throughout his life was with those features of individual plant species that were most relevant to survival in a given environment and against given competitors, and in particular those that could readily be assessed quantitatively. The best of his books—*The Reproductive Capacity of Plants* (1942) and *Weeds and Aliens* (1961)—and large numbers of papers in scientific journals, examine the survival-value of features of seed-production, or of vegetation multiplication and spread, in species of different habitats. They are packed with original data, especially of counts and weights of seeds produced by various species in various circumstances. Eleven of the fifteen papers published during the final ten years of his life are of this kind and the last of all, appearing in the year of his death at 92, included a table of estimated annual production of seeds by 49 different weed species 'based upon my own observations from random samples.'

It is relevant to reflect that Professor J. L. Harper's important book, *The Reproductive Biology of Plants*, is in many ways a continuation of *The Reproductive Capacity of Plants*, with a successful elucidation of many points left unexplained by Salisbury but with a considerable widening of scope and a far greater emphasis on experimentation. Characteristically, however, Salisbury had perceived many of what were still the outstanding problems in 1977.

Early in his career Salisbury became a member of the Royal Horticultural Society and was for many years a vice-president. He took great delight in gardening and after his marriage developed a notably attractive and botanically very interesting garden at his home Willow Pool, Radlett. *The Living Garden, or The How and Why of Garden Life*, a skilful popular exposition of the scientific basis of horticulture, appeared in 1945. It was immensely successful and led to the award of the Veitch Memorial Gold Medal of the RHS that same year, and he later received the society's Victoria Medal of Honour. His appointment to Kew was a fitting climax to his career.

Clear-headed, self-confident, determined and articulate, Salisbury was very much a committee man and served on innumerable councils, committees, delegacies and visiting groups. He was governor of several colleges and research institutions and a successful

chairman of many important public bodies. He was short of stature, lively and friendly in manner, but perhaps rather too fond of indulging his delight in lengthy exposition. He was an able administrator. In the later stages of his career, however, he spent much time on his outside commitments.

In 1917 Salisbury married Mabel Elwin-Coles, who died in 1956 after a long illness. There were no children.

A. R. Clapham

## C. T. Rajagopal

PROFESSOR Cadambathur Tiruvenkatacharya Rajagopal, a mathematician of considerable standing in India, and solely responsible for the survival in Madras of the Ramanujan Institute, died on 25 April 1978. Even more, perhaps, than his numerous original contributions to mathematics and its history (which were substantial by any standards), it is his devotion to the cause of mathematics in India and to the survival of the Institute (which he served in various capacities from 1951 to 1971) which made him a unique figure in an important period of the history of Indian science, deserving to be remembered by future generations of Indian scientists.

C. T. Rajagopal was born on 8 September 1903. His father, Cadambathur Tiruvenkatacharya, was in the judicial service of the Madras Presidency (now Tamil Nadu). His early education was in Madras; he took his Master's degree in the Madras Presidency College (where many of the most distinguished scientists of India, including Sir C. V. Raman, have been students). There he soon came under the influence of Professor K. Ananda Rau, himself a mathematician of great distinction, who had been G. H. Hardy's student and Ramanujan's contemporary in Cambridge. Ananda Rau is well known and remembered for his valuable contributions to the theory of Tauberian theorems, function-theory and the theory of Dirichlet series; and his tastes and interests were decisive for the orientation of Rajagopal's future scientific career.

After graduating from the Presidency College, Rajagopal joined the Madras Christian College as a lecturer. In 1951, T. Vijayaraghavan, on his appointment as director of the Ramanujan Institute, invited him to join its faculty; the story of Rajagopal coincides with that of the Institute for the following twenty-five years.

The Ramanujan Institute was founded in 1951 as a private institution

by the late Sir Alagappa Chettiar, a noted philanthropist of South India, as 'a small remembrance of a great man (Srinivasa Ramanujan). Its first director, T. Vijayaraghavan, was perhaps the most talented among G. H. Hardy's former students; he died at a comparatively early age in 1955; Rajagopal took over the directorship from him. Already at that time the financial status of the Institute seemed shaky, since Alagappa Chettiar's fortune was melting away; T. Vijayaraghavan's family was left unprovided for, and an appeal to the Prime Minister (the late Jawaharlal Nehru) had to be made in order to rescue them from utter poverty.

In April 1957, when Alagappa Chettiar died, the fate of the Institute hung in the balance; Rajagopal wrote to one of us (S.C.) that the Institute 'will cease to exist on the first of next month,' whereupon the addressee wrote to the Prime Minister, explaining the origin of the Institute and the seriousness of its condition. Nehru's prompt answer was refreshing: 'Even if you had not put in your strong recommendation in favour of the Ramanujan Institute of Mathematics, I would not have liked anything to happen which put an end to it. Now that you have also written to me on this subject, I shall keep in touch with this matter and I think I can assure you that the Institute will be carried on.'

And it was; but haltingly and precariously for the next twelve years. The responsibility for the Institute was divided between the U.G.C. (the federal University Grants Commission) and a reluctant University of Madras. There is no doubt that the Institute would not have survived had it not been for Rajagopal's continuing year after year with an uncertain appointment and often as the sole 'permanent' member of the Institute. In 1963 the future of the Institute and Rajagopal's own means of survival were so much in doubt that he wrote us in the following terms: 'In twenty-one years of service as a teacher (of which the first year was spent in Annamalai University and the rest in Madras Christian College), my salary rose from Rs.100 p.m. to about Rs.240 p.m. and earned for me a provident fund of nearly Rs.8,000. In the next twelve years of my service, in the Ramanujan Institute, my salary scale was Rs.500 - 50 - 800 until I was made a professor with effect from 1st March 1962 on Rs.850 p.m. in the present Madras University scale of Rs.800 - 50 - 1,250. However, my service in the Institute has left me with no savings and no retirement benefits. Thus, after a professional life of thirty and odd years, I find myself without the means to live in complete independence . . . '.

But Rajagopal did continue to serve the Institute for the following six years, and at long last, in August 1967, the Ramanujan Institute was finally adopted by the University of Madras, and in July 1969 a new director was appointed. Its subsequent fortunes do not concern us here; but this left Rajagopal with no pension; not a single *naya paisa* (the new half-penny), as he himself wrote; the undersigned, singly or jointly, must have written dozens of letters to various authorities during the years 1963-1978 to secure for him a modest stipend of Rs.500 p.m.

Despite such administrative and personal worries and frustrations, and without ever an opportunity for visiting any centre of mathematics in Europe or the United States, Rajagopal maintained an unabated output of competent, worthwhile mathematical research, well appreciated by co-workers in his favourite fields, chiefly Tauberian theorems and entire functions. In the latter part of his life, he became actively interested in the history of medieval Indian mathematics, to which he contributed a number of important papers, partly in collaboration with others; the last one, a joint article with M. S. Rangachari, appeared only a few weeks before Rajagopal's death, in C. Truesdell's well-known *Archive for History of Exact Sciences*, vol. 18, pp. 89-102, 1978. There it is shown that a number of power-series expansions for trigonometric and inverse trigonometric functions, discovered in the 17th century by Gregory, Newton and Leibniz (and independently, about the same time, by the Japanese Seki), had been known to Kerala mathematicians more than a century before.

Professor C. T. Rajagopal is survived by his wife, Mrs. Rukmini Rajagopal (now living in straitened circumstances, it must be pointed out, due to the lack of provision for a pension fund at the Ramanujan Institute). Tragically, Rajagopal's death occurred just as a grant had been approved to support the continuation of his and M. S. Rangachari's historical investigations, which were to appear eventually as a monograph on Kerala mathematics.

India may well have produced mathematicians of greater versatility and depth than C. T. Rajagopal, and will, one hopes, produce more such in the future; but none has served the cause of mathematics more selflessly nor with greater devotion. As both of us happen to have been personally associated, for many years, with this modest and talented man, we find it fitting that his long years of service be placed on record.

S. Chandrasekhar  
André Weil

## APPOINTMENTS VACANT

### UNIVERSITY OF SYDNEY RESEARCH FELLOW IN FUSION PLASMA PHYSICS

Applications are invited for a Postdoctoral position in fusion-orientated plasma physics. The appointment will be for two years and is funded by NERDDC. The appointee will work with the research tokamak under construction in the School of Physics and will be mainly responsible for the operation and development of diagnostic techniques, particularly laser scattering. The group possesses high power ruby and CO<sub>2</sub> lasers and a multichannel digital data acquisition system.

Salary will be in the range \$A15,786 to \$20,737 per annum. It is desired to fill the position early in July 1979.

Applications, including curriculum vitae, list of publications and names of three referees by **June 15, 1979** to Associate Professor J. Lehané, School of Physics, University of Sydney, NSW 2006, Australia, from whom further information available.

### UNIVERSITY COLLEGE OF SWAZILAND

Applications are invited for the post of  
**LECTURER**

in the

**DEPARTMENT OF BIOLOGY**

Candidates should possess at least an M.Sc. in Biology, although a Ph.D. would be desirable. Strong preference will be given to candidates who have had experience at the University level. A broad background of preparation will be an advantage. The appointee will be required to conduct lectures and laboratory periods in Biology, presently in years 1 and 2 of the B.Sc. course, Part I; and to perform standard duties in the day-to-day running of the Department's programme. Part II studies are scheduled to begin in August 1980, with the introduction of six three-credit courses in third year Biology, followed by six more in the following year. Preparation for this extension of programme will be included in the duties pertaining to the post.

Salary scale: Lecturer I, E5,940 to E7,860 per annum (£1 sterling=E1.75). The British Government may supplement salary by £1,650 to £2,184 per annum (sterling) for married appointee or £408 to £960 per annum (sterling) for single appointee (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; short-term contracts of 2-4 years; 25% gratuity in lieu of superannuation for first 2 years and 27½% for second 2 years; 10% inducement allowance for those not qualifying for supplementation from other sources; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University College of Swaziland, Private Bag, Kwaluseni, Swaziland, by July 10, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

858(A)

### UNIVERSITY OF WESTERN AUSTRALIA Perth LECTURESHIP IN INORGANIC CHEMISTRY

Applications are invited for appointment to the above position in the Department of Physical and Inorganic Chemistry. Preference will be given to applicants with experience in preparative and/or organometallic chemistry.

The appointee will be expected to share in the teaching of general inorganic chemistry and of organometallic chemistry at the undergraduate level, to lecture in his field of specialisation at senior undergraduate and at postgraduate levels and to carry out research for which time and good facilities are available.

The School of Chemistry occupies a well equipped building with machine, electronic and glass-blowing workshops. A wide range of equipment for physical measurements is available, and the University has good computing facilities. The staff of the Department of Physical and Inorganic Chemistry consists of fifteen members and there are 35 postgraduate and postdoctoral research workers.

The current salary range for a Lecturer is: \$A15,786 to \$A20,737 per annum. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependents family, removal allowance, study leave and long service leave and housing loan scheme.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by **June 30, 1979**. Candidates should request three referees to write immediately to the Staffing Officer.

961(A)

### PLANT BREEDING INSTITUTE

Maris Lane, Trumpington,  
Cambridge CB2 2LQ

**SCIENTIFIC OFFICER/  
HIGHER  
SCIENTIFIC OFFICER**

**FORAGE, OIL AND POTATOES  
DEPARTMENT**

A pathologist is required in the Forage, Oils and Potatoes Department to work on diseases of oilseed rape. This work is to be carried out in close co-operation with the oilseed rape breeder, Dr K. F. Thompson, and would involve developing mature-plant and seedling tests for resistance to stem canker, *Phoma lingam*, and light leaf spot, *Pyrenopeziza brassicae*. The work on canker would necessitate searching for new sources of resistance. The officer would also undertake glasshouse screening tests for resistance to clubroot, *Plasmodiophora brassicae*, and eventually possibly for *Alternaria*, *Botrytis* and *Peronospora*. A knowledge and interest in genetics would be useful as investigations on the inheritance of resistance to *Phoma* and *Pyrenopeziza* are planned.

Candidates should have a 1st or Upper 2nd Class Honours Degree specialising in Plant Pathology or equivalent; experience of Brassicas would be of an advantage.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Scientific Officer (£2,839 to £4,415 per annum) according to qualifications and experience. At least two years relevant postgraduate research experience is required for appointment as Higher Scientific Officer. Non-contributory Pension Scheme.

Applications with a curriculum vitae together with the names and addresses of three referees, quoting reference FOP.53, should be sent to the Assistant Secretary (Establishment) by June 22. Further particulars are available on request.

978(A)

### OIL EXPLORATION IN SOUTH AFRICA

Soekor, the South African National Oil Exploration Company, requires experienced personnel to join its exploration teams based in Johannesburg.

#### GEOLOGISTS

Minimum qualification: B.Sc. (Honours) Geology. The ideal candidate would be an experienced Petroleum Geologist or Well-site Geologist / Mudlogger. Knowledge of sedimentology, structural geology, basin evaluation, geophysics and geological log interpretation would be a strong recommendation.

#### GEOPHYSICISTS

Geophysicists of high calibre, suitably qualified and experienced in the field of reflection seismic interpretation and with a substantial knowledge of structural and sedimentary geology, are required.

#### PALYNOLOGISTS

Minimum qualifications: M.Sc. The work involves analysis of samples, ranging from Tertiary to Upper Jurassic. Appropriate experience in microspores and/or dinoflagellates will be an advantage. The successful candidate will form part of a team of micropalaeontologists.

Competitive salaries—negotiable. Benefits include assistance with travelling and resettling costs, holiday bonus, home ownership through low interest loans, group pension, life assurance and a low cost medical aid scheme.

Write, giving full personal, academic and experience details to: The Head, Personnel, Soekor, P.O. Box 3087, Johannesburg, 2000 South Africa. 867(A)

# Pathologists

We wish to recruit additional Pathologists, male or female, into the Safety of Medicines Department to join a team of Pathologists concerned in the safety evaluation of new drugs. Either medical or veterinary graduates.

The present Section of Pathology encompasses a full range of pathological techniques including electron microscopy, histochemistry, autoradiography and tissue culture. While experience in this field is desirable, those without immediate experience will be offered suitable training and encouraged to progress to higher qualifications.

The Pharmaceuticals Division is very attractively situated in rural North Cheshire,

within easy reach of a wide range of housing and main road and rail routes. Conditions of service, career opportunities, and assistance given to married persons in moving home are designed to attract and retain staff of high calibre.

Please write giving details of qualifications and experience, or requesting an application form

to:- Mr. M. F. Losse,  
Personnel Officer,  
Imperial Chemical  
Industries Ltd.,  
Pharmaceuticals Division,  
Mersey, Alderley Park,  
Nr Macclesfield,  
Cheshire.

Public Health Laboratory Service  
**Centre for Applied Microbiology and  
 Research, Porton Down,  
 Salisbury, Wiltshire**

**THE SPECIAL PATHOGENS REFERENCE LABORATORY** has the following vacancies:

## Chief Medical Laboratory Scientific Officer

Applications are invited for experienced virologists with expertise in tissue culture, serology, and animal work. Previous experience in handling viruses known to be pathogenic for man would be an advantage.

The successful candidate will be expected to contribute to the research and development programme and to the routine work of the laboratory. He/she will be responsible to the Director of the laboratory and will be engaged in the following aspects of work.

**(a) Reference work**

- (i) To assist with isolation and identification of viruses from acute samples submitted for diagnosis, particularly samples from suspected cases of Lassa/Marburg/Ebola fevers.

- (ii) To assist with serological investigations on convalescent sera.

**(b) Research and Epidemiology**

- (i) Research and Epidemiology of Haemorrhagic fever viruses, particularly Lassa, Marburg and Ebola. Other viruses to be investigated include Rift Valley Fever, Congo, Korean haemorrhage fever and certain arenaviruses.

- (ii) To produce high quality mono-specific immune sera for diagnostic procedures.

## Medical Laboratory Scientific Officer

Applications are invited for experienced virologists with particular expertise in tissue culture, immunofluorescent techniques, serology and experimental animal work. Previous experience in the handling of viruses known to be highly pathogenic for man would be an advantage.

The successful candidate will be expected to contribute to the research and development programme and to the routine work of the laboratory. He/she will be responsible to the Director of the laboratory and will be engaged in the following aspects of work.

1. To assist in routine diagnosis either through virus isolation and/or by serological methods of severe viral infections.
2. To assist in the development of new and improved techniques for rapid diagnosis of viral infections.
3. To produce diagnostic reagents for use in regional laboratories.
4. To assist in research activities as directed by the Director and Deputy Director of the laboratory.

**N.H.S. terms and conditions of service. Applicants must be State Registered.**

**Salary scales:** Chief M.L.S.O., £5,472 to £6,192; M.L.S.O., £3,261 to £4,680.

These posts may be discussed with Dr E. Brown, 0280-610391, ext. 326.

Applications, in writing, giving full details of experience, qualifications and the names and addresses of two referees to: Mrs M. Bushby, Personnel Officer, C.A.M.R.

Service Board.**

## university of wales university college of swansea

### Senior Research Assistant

Applications are invited from persons with or just completing a Ph.D. for the post of **Senior Research Assistant in the Department of Botany and Microbiology**. The successful applicant will work with Professor P. J. Syrett on the nitrogen assimilation of marine phytoplanktonic algae with financial support from N.E.R.C. Applicants should have experience and interests in biochemical cellular physiology.

The appointment, which will date from October 1, 1979 and will be for one year in the first instance with the possibility of renewal for a further two years, will be on a scale up to £4,776 per annum, plus U.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (two copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by Friday, June 8, 1979. 876(A)

## UNIVERSITY OF THE WEST INDIES—JAMAICA

Applications are invited for the post of  
**LECTURER/  
 ASSISTANT LECTURER**

in the

### DEPARTMENT OF ZOOLOGY

Whilst applications are invited in any field of Zoology, preference may be given to a well qualified applicant with interests in ecology.

**Salary scale (under review):** Lecturer, J\$8,913 to J\$13,917 per annum; Assistant Lecturer, J\$7,236 to J\$7,926 per annum (£1=J\$3.60). Family passages; F.S.S.U.; Study and Travel Grant; Unfurnished accommodation will be let by the University at a rental of 10% of salary, or a housing allowance of 20% of salary will be paid.

Detailed applications (three copies) with curriculum vitae and naming three referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 859(A)

## LIVERPOOL POLYTECHNIC

### DEPARTMENT OF BIOLOGY

### S.R.C. RESEARCH TECHNICIAN

**Salary Scale:**

£2,511 to £2,967 plus £312 per annum  
 To work for up to three years on the genetics and molecular biology of photosynthetic bacteria.

Applicants should have or expect to obtain a degree/H.N.C. in a biological subject including some experience of microbial genetics.

Further details may be obtained from Dr V. A. Saunders (Liverpool Polytechnic, Department of Biology, Byrom Street, Liverpool L3 3AF. Tel: 051-207 3581, Ext: 6) to whom applications, including a curriculum vitae and the names of referees, should be sent.

Closing date: 14 days from the date of this publication.

Please quote reference LP/291.

935(A)

## THE UNIVERSITY OF THE SOUTH PACIFIC

Applications are invited for the post of

### SENIOR LECTURER/ LECTURER IN PHYSICS (Post 79/40)

Applicants should have a doctorate (or equivalent research experience) in Physics or a closely related discipline as well as teaching experience. The appointee will be required to contribute to the teaching and development of undergraduate courses in pure and applied physics and in related interdisciplinary areas such as science. Current research interests in physics are environmental physics; renewable energy supplies; telecommunications and ionospheric physics and the appointee will be expected to pursue research in one of these areas. Preference will be given to applicants with interests in either environmental physics or renewable energy supplies but applicants in any of the above fields will be considered. There are opportunities for consultancy work in the University Region through the projects of the University's Institute of Natural Resources and Marine Resources. Applicants should be available by January 1980.

**Salary scales:** Senior Lecturer: F\$11,960 to F\$14,135 per annum; Lecturer: F\$8,175 to F\$11,563 per annum. (£1=F\$1.74.) The British Government may supplement salaries in range £1,842 to £2,796 per annum (sterling) for married appointees and £444 to £1,164 per annum (sterling) for single appointees (reviewed annually and normally free from tax and provide children's educational allowances and holiday visit passages. Family passages; gratuity 15% of basic salary; superannuation; partly furnished accommodation at maximum rental of 12% of salary (under review); appointment allowance; contract for 3 years and renewable by mutual agreement.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, University of South Pacific, P.O. Box 1168, Suva, Fiji, no later than June 22, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 825(A)

## UNIVERSITY OF NATAL DEPARTMENT OF GEOLOGY DURBAN

Applications are invited from suitably qualified persons, regardless of race or national origin for appointment to the post of

### LECTURER

or

### SENIOR LECTURER

in

### ENGINEERING GEOLOGY

**Salary in the range:**

**Senior Lecturer:**

R11 400 to R15 600 per annum

**Lecturer:**

R8 100 to R13 200 per annum

In addition to teaching duties the person appointed will be expected to be active in, and to supervise, research. There will be considerable opportunities to reorganise and co-ordinate existing courses in engineering geology. An interest in hydrogeology may be an advantage.

The grade of appointment and commencing salary notch will depend on the qualifications and experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, 4001, with whom applications, on the prescribed form, must be lodged not later than July 30, 1979, quoting the reference Adv. D33/79.

# Careers for young people in Research and Development

Redland Technology is a member of Redland Limited, the multi-national group of Companies which is principally concerned with the manufacture of building and construction materials.

Due to planned expansion, the New Technology and Product Development Centre at Horsham in Sussex has a number of immediate vacancies, as well as vacancies for additional staff to be appointed later in the year.

We are looking for men or women to be appointed as Support staff to our Materials Technologists working in a number of different disciplines. These positions would suit either school leavers with good 'O' or 'A' levels in Physics or Chemistry, or candidates with some experience in industry and relevant qualifications.

These jobs are interesting and varied; main duties will involve carrying out experimental work, testing and measuring under the control of a Materials Technologist. It is company policy to train support staff with a view to promotion to Technologist when the appropriate academic qualifications have been attained and, as such, suitable candidates will be offered day release courses to study. In addition, opportunities will arise to participate in both external and in-house training courses.

The Centre is based in a country environment on the outskirts of Horsham where working conditions are good.

Salaries are realistic and will depend initially on age and qualifications. Other benefits include a subsidised canteen, generous sick pay scheme, four weeks holiday a year and a Company bus service from Horsham.

Please apply for an application form and further details of the vacancies either by writing to or telephoning:

R. A. G. Poulton (Ref 7/79), Commercial and Personnel Manager,  
Redland Technology Limited, Graylands, Horsham, Sussex. Tel: Horsham 2351.

## Redland Technology

911(A)

## Centre for Applied Microbiology & Research, Porton Down, Wilts.

### Pathogenic Microbes Research Laboratory

## Top Grade Microbiologist

An experienced microbiologist is required in the above laboratory, which is concerned with research into mechanisms of microbial pathogenicity. A large proportion of the laboratory's research effort is currently directed to background studies for the development of an improved vaccine against *Bordetella pertussis*. Other programmes involve the antigenic changes related to growth conditions of bacteria, and studies of the mixed bacterial populations present in the mouth and the gut.

The successful applicant will have extensive experience in the study of pathogenic microbes, and a knowledge of one of the following fields would be particularly advantageous; continuous culture, bacterial cell wall chemistry, adhesion of microbes to cell surfaces.

## Senior Grade Microbiologist

The person appointed will carry out studies in continuous culture of mixed bacterial populations derived from the mouth, gut and respiratory tract. A knowledge of the isolation and characterisation of organisms derived from these ecosystems would be an advantage. Applicants should possess a postgraduate qualification and the ability to conduct a research programme.

## Medical Laboratory Scientific Officer

A young graduate or well qualified technician with experience in microbiology and/or biochemistry is required to assist in the study of the growth of pathogenic bacteria in continuous culture.

## Medical Laboratory Scientific Officer

A research technician, having a degree or H.N.C., is required to join a group working on antimicrobial defence mechanisms. Applicants should have had training and experience in immunology, microbiology or microbial biochemistry, together with experience of immunological techniques, particularly those relevant to cellular studies.

Salary Scales: Top Grade Microbiologist £8,877 to £10,347.

Senior Grade Microbiologist £5,451 to £6,837.

Medical Laboratory Scientific Officer £3,261 to £4,680.

N.H.S. terms and conditions of service will apply. Further details of the posts can be obtained from Professor D. O. Ellwood or Dr A. Baskerville, telephone Idmiston 610391.

Applications including curriculum vitae and the names and addresses of the referees should be sent to Mrs M. Bushby, Personnel Officer, CAMR, Porton Down, Salisbury, Wilts. Closing date for applications June 14, 1979. 912(A)

**PHLS**

**Public Health Laboratory Service Board.**

## THE UNIVERSITY OF LEEDS DEPARTMENT OF METALLURGY

Applications are invited for a post of

### EXPERIMENTAL OFFICER

to work in

### ELECTRON MICROSCOPY

to take overall responsibility for the electron optical facilities in the Department of Metallurgy. These facilities comprise three transmission microscopes, a scanning microscope with microanalytical attachment, and a photo-emission electron microscope. The post involves supervision of the maintenance of the instruments, training of operators, and development of the techniques in their application to Materials Science. Applicants should have graduate or equivalent qualifications and should have had considerable practical experience in electron microscopy. It is hoped to make an appointment with effect from October 1, 1979.

Salary at an appropriate point on the IB scale for Other Related Staff (£3,775 to £6,355 per annum) (under review with effect from October 1, 1979), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 70/3/D. Closing date for applications: June 21, 1979. 893(A)

## UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of

### RESEARCH ASSISTANT

in Neurobiology in the DEPARTMENT OF ZOOLOGY. Applicants should hold or expect to obtain this year a first or upper second class honours degree and will work with Dr R. S. Pickard on a project, funded by an S.R.C. grant, concerned with the anatomy and electrophysiology of the honeybee brain. The successful applicant will be encouraged to register for a higher degree subject to normal University regulations. Salary: £3,689 per annum. Duties to commence September 1979.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars are available. Closing date July 1, 1979. Reference 1797. 946(A)

## BIRKBECK COLLEGE (University of London)

Application invited for RESEARCH ASSISTANT (Chemistry) on S.R.C. —project involving the application of Extended X-ray Absorption Fine Structure Spectroscopy (EXAFS) to anti-cancer drugs, anti-inflammatory drugs and protein complexes, using the Synchrotron Radiation Facilities at Daresbury and Hamburg. Data analysis will be on an interactive computer graphics system at Birkbeck, linked directly with the IBM 370/165 computer at Daresbury.

Appointment for up to three years from October 1, 1979; starting salary £5,412 per annum (including London Weighting). May suit postdoctoral physicist or physical chemist with an interest in biomedical problems. Applications (curriculum vitae and the names of two referees) should be sent to Dr P. J. Sadler, Chemistry Department, Birkbeck College, Malet Street, London, WC1E 7HX (Tel: 01-580-6622, ext. 262 or 326), from whom further details are available. 941(A)

## UNIVERSITY OF EXETER DEPARTMENT OF BIOLOGICAL SCIENCES (N.E.R.C. Research Project) POSTDOCTORAL RESEARCH ASSISTANT and TECHNICIAN (Grade 3)

Applications are invited for the posts of PDRA and Technician to investigate the effects of soil animals on microbial populations and nutrient cycling processes under the direction of Dr J. M. Anderson.

The PDRA post will be in the salary range £4,232 to £4,776 p.a. Applicants should have experience in soil microbiology and/or biochemistry.

The technician (salary range £2,931 to £3,336 p.a.) will be responsible for chemical analysis and support of the above position.

Both appointments will be for one year in the first instance, with the possibility of renewal for a further two years, commencing October 1, 1979.

Applications, stating the names of two referees, to Dr J. M. Anderson, Department of Biological Sciences, Hatherly Laboratory, Prince of Wales Road, Exeter, from whom further particulars may be obtained. Closing date for receipt of applications June 22, 1979. 953(A)

## UNIVERSITY OF CAMBRIDGE

### DEPARTMENT OF CLINICAL BIOCHEMISTRY

Applications are invited for a

### UNIVERSITY LECTURESHIP (Non-clinical)

in the Department of Clinical Biochemistry at Addenbrooke's Hospital, Cambridge. It is hoped to appoint a person whose main interest is in immunological aspects of cell membrane structure, function and pathology.

The appointment will be for three years with the possibility of reappointment to the retiring age.

The pensionable scale of stipends for a University Lecturer, not ordinarily resident in College, is £5,850 a year rising by twelve annual increments to £9,000. There is no grade of Senior Lecturer.

Further information about the duties and conditions of the appointment may be obtained from Mr J. F. Howe, Clinical School Office, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QO, to whom applications (fifteen copies) together with the names of three referees, should be sent so as to reach him not later than June 25, 1979. 974(A)

## UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENTS OF ORGANIC CHEMISTRY AND MICROBIOLOGY RESEARCH ASSOCIATE

Applications are invited for a Medical Research Council sponsored post involving a chemotaxonomic study of clinically-significant micro-aerophilic actinomycetes and related bacteria in collaboration with Dr M. Goodfellow and Dr D. E. Minnikin. Candidates should have completed a Ph.D. or have equivalent research experience and preferably have expertise in lipid analyses and chromatographic techniques. The appointment will be for three years at a commencing salary of £4,382.

Applications, including curriculum vitae and names of two referees should be sent by June 15, 1979 to Dr D. E. Minnikin, Department of Organic Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 877(A)

# AHMADU BELLO UNIVERSITY ZARIA, NIGERIA

FACULTY OF MEDICINE  
Vacancies exist at various levels  
FROM PROFESSOR TO  
LECTURERS

in the following departments: Radiology, Chemical Pathology, Immunology (in Medicine), Anaesthesia, Anatomy, Medicine (Neurology, Endocrinology), Pathology (Morbid Anatomy), Paediatrics, Surgery, Physiology.

**SALARIES:** Professor, G.L.16, N11,568 to N12,720; Senior Lecturer, G.L.13, N8,064 to N9,024; Lecturer I, G.L.12, N7,404 to N8,052; Lecturer II, G.L.10, N5,760 to N6,732. (N1= approximately 0.97p.)

**CONDITIONS OF SERVICE:** Appointments are either pensionable (for Nigerians only) or on contract of two years in the first instance. Fringe benefits include part-furnished accommodation, or housing allowance in lieu of accommodation, and a 25 per cent Contract Addition is payable to all expatriates.

**METHOD OF APPLICATION:** Candidates should send 4 copies of their curriculum vitae to the Principal Assistant Secretary (Recruitment), D001/606 Nigerian Universities Office, 180 Tottenham Court Road, London W1P 9LE, as soon as possible, preferably in time to arrange interviews at the end of May. The curriculum vitae should give the following information: Post desired, full name, date and place of birth, nationality, permanent address, telephone number, if any, current postal address and telephone number, if applicable, marital status, number and ages of children, educational institutions attended with dates, full qualifications plus copies of certificates, previous employment with dates, present employment with dates and salary, list of publications, names and addresses of three distinguished scholars in relevant field as referees, two passport photographs of self. Candidates are advised to request their referees to forward references on them directly to the London Office.

853(A)

# ICI/UNIVERSITY OF LEICESTER JOINT LABORATORY IN MOLECULAR GENETICS

The above laboratory has vacancies for postdoctoral molecular biologists to work on the expression of eukaryotic genes in bacteria. Applicants with experience relevant to the cloning of copy DNAs, such as the purification and translation of messenger RNAs or appropriate biochemistry, will be favoured.

Appointments will be for two years in the first instance, renewable for up to five years, with salaries on the scale of £4,232 to £7,145 (under review).

Applicants should send a detailed curriculum vitae and names of two referees to Professor W. J. Brammar, Department of Biochemistry, University of Leicester, Leicester LE1 7RH, from whom further details can be obtained.

818(A)

# SENIOR EDITOR, SCIENCE

Macmillan Education is a rapidly expanding Company within the Macmillan Group. The Publisher for the U.K. Secondary School Division is looking for a Senior Editor to run the Secondary School Science Programme. The successful applicant will ideally have a science degree and commissioning experience in educational publishing. He/she will be enthusiastic and possess initiative and a sound business acumen.

The job will be based at our Basingstoke offices and offers a competitive salary and Company Car.

Please write, with full career details including present salary to:

Tony Feldman, Publisher, Macmillan Education Limited, 4 Little Essex Street, London WC2R 3LF. 958(A)

# THE QUEEN'S UNIVERSITY OF BELFAST RESEARCH ASSISTANT DEPARTMENT OF MICROBIOLOGY & IMMUNOBIOLOGY

Applicants for this post should preferably have a first or upper second class honours degree in microbiology or a related science. Experience in the immunology of viruses and the use of tracer methods or in the physiology of anaerobic bacteria would be advantageous as research in these two fields are main interests in the department. The post is tenable for one year but may be renewable annually for a further five years. Salary scale (under review) £3,384 to £4,884 per annum with contributory pension rights under U.S.S.

Curriculum vitae, giving the names and addresses of two referees, should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: June 15, 1979. Please quote reference 79/N. 898(A)

# UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of  
**RESEARCH ASSISTANT**

in the DEPARTMENT OF ZOOLOGY. The post is supported by the N.E.R.C., to work on a project entitled "Intra-specific Mechanisms of Population Regulation in the Pine Aphid, *Cinara pinea* (Mordv.), with particular reference to the Role of Flight Behaviour". Applicants should possess or expect to obtain a good Honours degree in Zoology or related discipline and will be encouraged or register for a higher degree. The post is tenable for three years from August 1, 1979. Salary range: £3,689 to £4,232 per annum.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars are available. Closing date June 21, 1979. Reference 1792. 945(A)

# COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER

at the

# COMMONWEALTH INSTITUTE OF HELMINTHOLOGY The White House

103 St Peter's Street

St Albans, Herts., England AL1 3EW

**Duties:** Scientific Information Officer required in the Commonwealth Institute of Helminthology at St Albans to work on *Protozoological Abstracts*.

**Qualifications:** Essential qualifications are a degree in biology, several years postgraduate experience working on parasitic protozoa, a knowledge of at least one foreign language, the ability to write clear and concise English and an interest in bibliographical work.

**Salary:** The salary in the scale £2,839 to £5,448 (under review) plus Outer London Weighting and a compensatory allowance to offset personal contribution to superannuation.

**Application forms** and full particulars from:

Executive Director,  
Commonwealth Agricultural  
Bureaux,  
Farnham House,  
Farnham Royal,  
Slough SL2 3BN.

**Closing date for applications:** June 30, 1979. 957(A)

# NEW ZEALAND Scientist HEAD OFFICE

# Department of Labour

# DUTIES

To advise the Factory and Dangerous Goods and Explosives Inspectorates on all matters relating to chemical and other occupational health hazards and safety in industry, especially the hazards of dusts, liquids and gases (toxicity, explosibility and flammability) and other dangerous goods. The appointee will head a team of scientists. He or she will be required to travel within New Zealand to investigate accidents, incidents and problems.

The appointee will be expected to maintain close liaison with other Government departments and organisations to ensure a co-ordinated and informed approach to problems. Such liaison will extend to overseas organisations when necessary. The appointee must be capable of keeping up to date with world trends in relevant subjects and to research specific matters in depth. The appointee will be required to assist in preparing discussion drafts of new and revised legislation and Codes of Practice, and must have the ability to explain technical matters to non-technical persons on an individual or group basis. Some lecturing to staff will be required.

# QUALIFICATIONS

The position would particularly suit a chemical engineer or industrial chemist with a degree in one of these disciplines. Applicants with qualifications in other appropriate disciplines will be considered. Practical industry experience is highly desirable.

# SALARY

The salary payable will be up to \$NZ18,377 per annum plus a General Wage Order Adjustment of \$NZ365.00 per annum.

Interviews will be conducted during the first week of July by an officer from the Department of Labour in New Zealand.

Successful applicants will receive assistance with fares and transfer of personal baggage to New Zealand.

Full details and application forms can be obtained by writing to:

The Chief Migration Officer,  
New Zealand High Commission,  
New Zealand House,  
Haymarket, London SW1Y 4TQ

Quote reference IMM 1/14/1, in your enquiry.

Closing date for applications is June 18, 1979.

920(A)

# UNIVERSITY OF LEICESTER DEPARTMENT OF ZOOLOGY RESEARCH DEMONSTRATORSHIP

Applications are invited for a Research Demonstratorship tenable for three years commencing October 1, 1979. Candidates should have a good honours degree in Zoology or Biological Sciences, and a definite interest in carrying out research in the fields of Fish Behaviour or Cell Biology. The successful applicant will be required to register for full-time postgraduate studies towards the degree of Ph.D. in either of the above fields, and will be required to assist with demonstrating and tutorial work in the department for a maximum of 10 hours per week during term time.

Salary within the range £3,504 to £3,689 to £3,961 with superannuation benefits.

Applications with the names of two academic referees should be sent as soon as possible to Professor H. C. Macgregor, Department of Zoology, University of Leicester, Leicester LE1 7RH. 897(A)

# ROTHAMSTED EXPERIMENTAL STATION Harpden, Herts. AL5 2JQ SCIENTIFIC OFFICER

required in the Nematology Department to join a group working on the taxonomy and pathotypes of agriculturally important cyst-nematodes and their relatives, using morphological observation by light and scanning electron microscopy supplemented by experimental studies of host-range, hybridisation and other aspects of biology. Interest in taxonomy an advantage.

**Qualification:** Honours degree or equivalent in Biology, Zoology or Agricultural Zoology, or an ordinary degree with relevant experience.

**Appointment** in grade of Scientific Officer, salary scale £2,839 to £4,414 (Pay Award pending). Point of entry depending on qualifications and experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 398 by June 14, 1979. Further details on request. 964(A)

# CSIRO AUSTRALIA

## Postdoctoral Research Fellow

### Fuel Geoscience Unit Canberra Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

**Field:** PETROLEUM GEOBIOLOGY

**General:** The Fuel Geoscience Unit conducts research relevant to exploration for fossil fuels—coal, petroleum, natural gas and oil shale—and to their assessment and extraction. The Baas Becking Geobiological Laboratory in Canberra is supported jointly by CSIRO, the Bureau of Mineral Resources and the Australian Mineral Industries Research Association, and is well equipped for the microbiological studies envisaged. The project is expected to be of three years' duration (subject to continuation of support) and the successful applicant will work with the existing group at the Baas Becking Laboratory in Canberra.

**Duties:** Initiate and carry out a research programme, in coordination with existing projects, to develop surfactants and viscosifiers by microbial processes under conditions relevant to natural petroleum reservoirs. The aim of the work is to enhance the economically recoverable proportion of petroleum from certain Australian petroleum occurrences.

**Qualifications:** A PhD degree or equivalent qualification supported by evidence of research capacity. Experience in multidisciplinary projects would be an advantage.

**Salary:** Research Scientist/Senior Research Scientist \$A15,422—\$A22,405 pa.

**Tenure:** The position is available for 12 months initially with the possibility of extension(s).

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 604/162 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 23rd June, 1979.

Applications in U.S.A. and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

917(A)

## UNIVERSITY OF BIRMINGHAM

### DEPARTMENT OF GEOGRAPHY

### TWO RESEARCH ASSOCIATES

S.S.R.C. Funded Project on Moorland Change and Upland Management in U.K. National Parks

Applications are invited for two graduate research associates to work with Dr M. L. Parry on the airphoto-mapping and computer-assisted analysis of moorland change. The appointments require experience in the use of either aerial photographs or computers in geographical or allied research.

Appointment will be from October 1, 1979 for two years in the salary range £3,775 to £5,488 per annum, plus superannuation. Maximum starting salary will not exceed £4,333.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees, should be sent by Friday, June 8, 1979.

Please quote reference NH7.

924(A)

## UNIVERSITY OF SYDNEY

### LECTURESHIP IN MICROBIOLOGY

Candidates should have knowledge of basic microbiology. A higher degree or equivalent with teaching and research experience given preference. Administrative and industrial experience also taken into consideration.

Department's facilities are adequate for most fields of microbiology research, except animal virology. Present research programmes include aspects of cytophysiology, ecology, genetics, serology and biological nitrogen fixation.

Appointment to commence early 1980.

The position is expected to be filled by a probationary appointment of three years, capable of leading to tenure, but if all the University's requirements for tenure are deemed to be satisfactorily met, tenure may be granted at the time of appointment.

Salary Range: \$A15,786 to £20,737 per annum.

Applications including curriculum vitae, list of publications and names of three referees by June 15, 1979 to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Adpts.), 36 Gordon Square, London WC1H 0PF.

962(A)

## SHEFFIELD CITY POLYTECHNIC

### DEPARTMENT OF BIOLOGICAL SCIENCES

### RESEARCH ASSOCIATE IN BIOLOGICAL SCIENCES

Salary Scale:

£4,101 to £6,558 per annum

This is one of two posts of Research Associate created in the Polytechnic to provide leadership and direction of research in specific areas. The research activities of the Department are concentrated mainly in the areas of Microbial Biochemistry, Animal Physiology and Biochemistry.

Applicants must be well qualified and experienced in one of the above areas and have previous experience of research supervision. Recent industrial experience would be advantageous.

The appointment is for a fixed period of three years.

Requests for an application form, in writing only please, to the Recruitment Section of the Personnel Department, Sheffield City Polytechnic, (Dept. N), Halfords House, Fitzalan Square, Sheffield S1 2BB. Completed forms should be returned by June 8, 1979.

921(A)

## FACULTY OF MEDICINE

### DEPARTMENT OF MEDICINE

### AHMADU BELLO

### UNIVERSITY

### ZARIA

R/APP/108/23/Vol. II

Applications are invited for the post of

### SENIOR LECTURER

(in Clinical Immunology)

and

### LECTURER

(in Clinical Immunology)

For the post of SENIOR LECTURER candidates must be medically qualified, have 10 years' postgraduate experience and hold a recognised higher degree in medicine. Some previous experience in clinical immunology is required. Both medically qualified and science graduates will be considered for the post of LECTURER. Medically qualified graduates must hold a recognised higher degree in medicine but previous experience in immunology is not essential. Non-Medical qualified candidates must hold a higher degree and have had considerable experience in immunology. Successful candidates will be expected to help in the teaching of immunology to undergraduates and postgraduates and to assist in the running of a clinical immunology service for the Ahmadu Bello University group of hospitals. There are excellent facilities for research in a well-equipped immunology laboratory. The current research programme of the laboratory, which is supported by the United Kingdom Medical Research Council, is concerned with immunology aspects of some of the locally important infectious diseases.

**SALARIES:** Senior Lecturer, GL.13, N9,064 to N9,024; Lecturer I, GL.12, N7,404 to N8,052; Lecturer II, GL.10, N5,760 to N6,732. N.B.: N1 = approx. 79p.

The appointment may be either on fixed term normally of two years contract, renewable by mutual agreement or till the retiring age of sixty (60). Economy-Class air passage will be paid for appointee, wife and up to five (5) children on appointment, on home leave by overseas staff every second year and on termination. Pension Scheme with a grant for local travel in intervening years, are the fringe benefits, and partly furnished accommodation at rental not exceeding 7 per cent of salary will be provided. Detailed applications, three (3) copies including a curriculum vitae with photocopies of all certificates and naming three (3) referees should be forwarded by airmail, not later than June 29, 1979 to the Registrar, Ahmadu Bello University, Zaria, Nigeria. Applicants resident in U.K. should also send one copy to N.U.C. London Office, 180 Tottenham Court Road, London W1P 9LE. 910(A)

## UNIVERSITY COLLEGE OF SWAZILAND

Applications are invited for the post of LECTURER

in the

### DEPARTMENT OF ANIMAL PRODUCTION AND HEALTH

Candidates should possess a Master's degree (or higher) in any branch of Animal Production. Preference will be given to those who have specialised in Animal Nutrition. Candidates should have had teaching experience, preferably in a University or College in a developing country. The appointee will be required to teach the subject matter of his/her competence at both the degree and diploma levels; to prepare teaching materials and aids; within the limits of the available time, to carry out research and development activities; to carry out related work assigned by the Head of Department or the Dean of the Faculty or any other competent authority.

Salary scale: E5,940 to E7,860 per annum (£1 sterling = E1.75). The British Government may supplement salary Government may supplement salary in range £1,650 to £2,184 per annum (sterling) for married appointee and £408 to £960 per annum (sterling) for single appointee (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; 2-4 year contracts; if appointment for limited period 25% gratuity in lieu of superannuation for first 2 years and 27½% for second 2 years. 10% inducement payable for those not obtaining supplementation from other sources; education allowance; reasonable rented accommodation; biennial leave.

Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University College of Swaziland, Private Bag, Kwaluseni, Swaziland, by July 4, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 860(A)

## IMPERIAL COLLEGE FIELD STATION

### Silwood Park, Ascot

### TECHNICIAN GRADE 5

Required to work on an MRC sponsored project.

"The Sexual Development of Malarial Parasites." Suitably qualified persons should have experience in one of the following areas:— Tissue Culture, Electron Microscopy or Biochemistry. The appointment is for approximately two and a half years initially.

Starting salary £3,474 to £4,056. Five weeks annual leave, plus extra days at Christmas and Easter.

Apply with curriculum vitae and the names of two referees to Dr R. E. Sinden, Imperial College Field Station, Ashurst Lodge, Ascot, Berks by May 31, 1979. 909(A)

## UNIVERSITY OF OXFORD

### DEPARTMENT OF AGRICULTURAL SCIENCE

### RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant in Soil Science tenable for two years from October 1, 1979. The salary will be on the grade 1B scale (£3,689 to £6,108 per annum).

The successful applicant will be expected to initiate studies in solute transfer between soil aggregates and surrounding voids. A background in the physical sciences with a knowledge of soil science would be suitable.

Applications giving full details of qualifications and experience and the names and addresses of two referees should be sent to the Administrator, Department of Agricultural Science, Parks Road, Oxford OX1 3PF by June 30, 1979. 976(A)

# UNIVERSITY OF AUCKLAND NEW ZEALAND

Applications are invited for the following full-time teaching position. Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments) at Auckland University, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Applications, in accordance with 'Method of Application', will be accepted at any time up to **June 30, 1979**.

Commencing salaries in accordance with qualifications and experience will be established within the Lecturers scale which is at present NZ\$11,529 per annum rising by annual increments to \$14,250 per annum. In normal circumstances, a Lecturer whose services have proved satisfactory to the Council may expect in due course to be given the status of a Senior Lecturer, salary maximum NZ\$16,780 per annum. At present all salaries are supplemented by a General Wage Order of NZ\$365 per annum.

## ANTHROPOLOGY

### Lectureship in Physical Anthropology

It is hoped to recruit a human population biologist but palaeoanthropologists will also be considered. Applicants should be competent in teaching genetics, ecology and evolutionary theory. The ability to teach quantitative methods would be an advantage. The teaching of these topics is integrated into the Prehistory and Physical Anthropology Section of the Department of Anthropology. 959(A)

# CITY OF LONDON POLYTECHNIC DEPARTMENT OF BIOLOGICAL SCIENCES ELECTRONICS TECHNICIAN GRADE 5

The City of London Polytechnic require, as soon as possible, an Electronics Technician for the design and construction of electronic physiological and neurophysiological apparatus for teaching and research, together with day-to-day servicing of neurophysiological teaching laboratory, and supervision of the electronics workshop. Candidates should possess an H.N.C. in an appropriate field.

The vacancy exists in our Biological Sciences Department which is located at Calcutta House, Old Castle Street close to Aldgate and Aldgate East Underground stations.

Starting salary, which will depend on qualifications and experience, will be within the scale of £3,675 to £4,212 inclusive (under review).

Further details and an application form can be obtained from the Staff Records Officer, City of London Polytechnic, 117/119 Houndsditch, London EC3A 7BU. Please quote reference number 79/18. 969(A)

## POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post supported by MRC to work with Dr J. Mowbray on adenine nucleotide sequestration in cardiac muscle (see Biochem. J. 176, 485 (1978)). The sequestered material has been located and the project is to establish its chemical nature and to characterise the enzymes involved. Appointment will be for two years at a starting salary (range 1A) of £4,261 plus £502 London Allowance. Enquiries and applications (including a curriculum vitae and names of two referees) should be sent to Dr J. Mowbray, Biochemistry Dept. University College London, Gower Street, London WC1E 6BT. 967(A)

# THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a temporary post of

## RESEARCH FELLOW

in the above Department to work with Dr D. A. Harris on a project supported by the S.R.C. on enzymology of ATP synthesis by mitochondria and/or Chloroplasts. The work will involve studies of chemical modification of isolated and membrane proteins, and rapid reaction kinetics. Candidates should already possess, or expect to be awarded, a Ph.D. degree, within the next few months. Experience with, or interest in computerised systems would be an advantage. The appointment will be made for a fixed period of three years with effect from October 1, 1979 (or as soon as possible thereafter).

Starting salary in the range £4,382 to £4,882 on the 1A scale for Research and Analogous Staff (£3,883 to £6,555). The salary scale is under review with effect from October 1, 1978.

Informal enquiries about the post will be welcomed by Dr D. A. Harris (Telephone (0532) 36171, ext. 86).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/22/D. Closing date for applications: June 15, 1979.

764(A)

# GLASSHOUSE CROPS RESEARCH INSTITUTE

requires a

## PLANT BIOCHEMIST

or

## PHYSIOLOGIST

in the

## PLANT PHYSIOLOGY DEPARTMENT

to initiate a research programme on mechanism(s) through which responses to light are controlled by phytochrome and other photomorphogenic pigments.

Appointment in Higher Scientific Officer/Senior Scientific Officer grade depending on qualifications and experience. Salary scales £4,101 to £5,448 (H.S.O.) or £5,154 to £6,898 (S.S.O.), under review. Applicants should have First or Upper Second class Honours degree in Botany or Plant Biochemistry with at least two years postgraduate experience. Non-contributory superannuation scheme. Further details and application forms on request. Applications giving full biographical details and names and addresses of two referees to Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, West Sussex BN16 3PU, by May 31, 1979. 899(A)

# UNIVERSITY OF BRISTOL

Applications are invited for the post of

## TECHNICIAN GRADE 5

within the

## DEPARTMENT OF SURGERY

The person appointed would be in technical charge of the department's Immunology Laboratory which is sited at the University Medical School. This laboratory is concerned with the investigation and treatment of cancer. Minimum qualifications: H.N.C. or equivalent.

Salary £3,474 to £4,056 per annum according to age, qualifications and experience (scale under review).

Applications in writing, with the names of two referees, to Mr F. E. Badrick, Chief Technician, Department of Surgery, Bristol Royal Infirmary, Bristol BS2 8HW. Closing date: May 31, 1979. 918(A)

# Medical University of South Carolina DEPARTMENT OF ANATOMY

Three positions are available from September 1, 1979.

## Assistant professor

with substantial teaching experience in gross anatomy and neuroanatomy. The individual should have several years postdoctoral experience and research interests should focus on retinal development and plasticity in the developing rodent visual system.

## Assistant professor

with broad teaching experience in neurobiology. Several years of postdoctoral experience are required and research interests should centre around response properties and intracellular injection of visual cortical neurons. This is a temporary position.

## Instructor

with teaching experience in gross anatomy and neuroanatomy. Some postdoctoral experience is required. Research interests should include development of the avian visual system and transplantation of the developing rodent visual system. This is a temporary position.

Closing date for applications: May 23, 1979. Send curriculum vitae to: Dr. R. D. Lund, c/o Office of the Dean, College of Medicine, Medical University of South Carolina, 171 Ashley Avenue, Charleston, South Carolina 29403. An Equal Opportunity/Affirmative Action employer.

W130(A)

# ST. CHARLES' HOSPITAL EXMOOR STREET, LONDON W10 MEDICAL LABORATORY SCIENTIFIC OFFICER/JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICER BIOCHEMISTRY DEPARTMENT

The Laboratory has a special responsibility for hormone radioimmunoassay but full training is available within the District. Applicants should be state registered although a junior medical laboratory scientific officer studying for H.N.C. (Clinical Chemistry) will be considered.

For further details telephone Mr Vermont, Senior Chief Medical Laboratory Scientific Officer, 01-969 2488, ext. 357.

Application form available from Personnel Department, tel. no. 01-969 2488, ext. 354. 856(A)

# RESEARCH ASSOCIATE Biochemistry of Genetic Recombination

Postdoctoral position at University of Maryland, Baltimore County, for *in vivo* and *in vitro* studies of DNA recombination and repair. Extensive interaction and collaboration with molecular biology groups at nearby National Institute of Health and Johns Hopkins University. Experience in molecular genetics or nucleic acid biochemistry highly desirable but not essential. To begin Summer 1979; earlier or later dates possible. Salary: \$14,000 to \$15,000, plus fringe benefits. Candidates with M.S. degree and demonstrated capacity for independent research will be considered. Send vitae and two (2) letters of recommendation to: Dr John Hays, Department of Chemistry, UMBC, Catonsville, Md., U.S.A., 21228. UMBC is an Affirmative Action/Equal Opportunity Employer. W129(A)

# UNIVERSITY OF MELBOURNE CHAIR OF AGRICULTURAL ENGINEERING

Applications are invited for appointment to the Chair of Agricultural Engineering which will become vacant in April 1980, on the retirement of Professor C. G. E. Downing who was the first occupant of this chair.

SALARY: expected to be \$A33,061 per annum.

Further information about the position and the duties involved, including details of application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment, is available from the Registrar, or from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close on **September 30, 1979**. 968(A)

UNIVERSITY OF BASLE  
DEPARTMENT OF PRE- AND PROTOHISTORY

Applications are invited for the

## Professorship in Prehistory and Environmental Archaeology

VACANCY AFTER SEPTEMBER 1980

Duties include:

**Teaching:** Palaeolithic, Mesolithic and if possible Neolithic periods, in the context of the ecology of the Pleistocene and Holocene; technology and mining in pre- and protohistorical times; archaeozoology; excavations.

**Research:** In the subjects taught.

Collaboration with the protohistorical and Roman section.

Applications including curriculum vitae, list of publications and teaching experience should be submitted before end of July 1979 to the Dean of the Faculty of Science.

Address: Dekanat der  
Philosophisch-Naturwissenschaftlichen Fakultät  
der Universität Basel  
Klingelbergstrasse 70  
CH-4056 BASEL. W124(A)

INSTITUTE OF  
LARYNGOLOGY AND OTOLOGY  
Gray's Inn Road, London WC1X 8DA  
**RESEARCH ASSISTANT**

required to join a team investigating hearing processes. The appointment will be for one year during which time the successful applicant will undertake an accoustical study involving hearing impaired subjects. Applicants should have a good science degree and a working knowledge of electronic measurement and computer processing techniques.

Salary: £4,152 per annum inclusive.

The appointment is in association with the Nuffield Hearing and Speech Centre.

Write for application form and job description to:

**Dr D. T. Kemp**  
Department of Audiology  
Institute of Laryngology and Otology

977(A)

THE POLYTECHNIC  
HUDDERSFIELD  
DEPARTMENT OF LIFE SCIENCES  
**PRINCIPAL LECTURER, SENIOR LECTURER OR  
LECTURER II—HUMAN ECOLOGY**  
Ref: ACA/343

Preference will be given to candidates with teaching and/or industrial experience and a proven research record and possessing a first degree in a Biological subject and a higher degree in Agriculture or Biological resource management. Experience of developing countries particularly in tropical resources would be advantageous.

Staff are expected to undertake activities, including research, in addition to teaching duties.

Salary: Principal Lecturer £7,047 to £7,818 (Bar) to £8,844.  
Senior Lecturer £6,051 to £7,065 (Bar) to £7,572.  
Lecturer II £4,101 to £6,558.

Further details and application forms, which should be returned by June 8, 1979, from the Personnel Office, The Polytechnic, Queensgate, Huddersfield HD1 3DH (Telephone 0484 22288 Ext 2225). 907(A)

CHAIRMAN  
of the  
DEPARTMENT OF  
PHYSIOLOGY  
WAYNE STATE  
UNIVERSITY  
SCHOOL OF MEDICINE

Creative and energetic leader to assume the chair of this large and More than 20 faculty members, large and modern research and teaching facilities. Applicants diverse department July 1, 1980, should have an established and productive research record, experience in teaching and administration, to be able to assume responsibility for the medical, allied medical and graduate teaching programmes of the department. Sex, race, religion or national origin will not be factors in the selection process.

Interested persons should reply by July 1, 1979 to:

Dr Bernard H. Marks,  
Department of Pharmacology,  
Wayne State University,  
School of Medicine,  
Detroit, Michigan 48201.  
W122(A)

UNIVERSITY OF  
NEWCASTLE UPON TYNE  
DEPARTMENT OF  
ORGANIC CHEMISTRY  
**RESEARCH ASSOCIATE**

Applications are invited for a Science Research Council sponsored post involving the systematic analysis of mycobacterial mycolic acids and related long-chain compounds in collaboration with Dr D. E. Minnikin. Candidates should have completed a Ph.D. or have equivalent research experience, hold a first class degree in Chemistry and preferably have expertise in the analysis of long-chain fatty acids. The appointment will be for three years at a commencing salary of £4,382.

Applications, including curriculum vitae and names of two referees, should be sent by June 15, 1979 to Dr D. E. Minnikin, Department of Organic Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 873(A)

**RESEARCH FELLOWS IN  
ASTRONOMY  
ROYAL OBSERVATORY  
EDINBURGH**

There are vacancies at the Royal Observatory Edinburgh for Research Fellows. The Observatory is responsible for three national astronomical facilities; the UK 1.2m Schmidt Telescope in Australia, the 3.8m Infrared Telescope in Hawaii and the COSMOS machine at Edinburgh. In Edinburgh there are several thousand plates from the UK Schmidt Telescope and photographic laboratories equipped to exploit this data bank. There are extensive facilities for developing and testing new instruments.

The Royal Observatory manages and operates the telescopes in Australia and Hawaii, and some of the Research Fellows are expected to spend time abroad as members of the operating teams. Others are based in Edinburgh, where there are excellent library, computing and workshop facilities. The Observatory in Edinburgh also houses the Astronomy Department of Edinburgh University.

Appointments are generally for a period of three years. A fixed stipend is paid, ranging from £3,695 to £8,466 per annum.

Further details and application forms from the Personnel Officer, Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ. 922(A)

**NATURAL ENVIRONMENT  
RESEARCH COUNCIL  
INSTITUTE FOR MARINE  
ENVIRONMENTAL RESEARCH  
PLYMOUTH  
ELECTRONICS  
DEVELOPMENT  
ENGINEER/PHYSICIST**

To take charge of a small Electronics Group, design and develop new instrumentation for marine research, advise and assist staff of the Institute regarding their instrumentation requirements and maintain existing equipment.

Qualifications: A degree or HNC/HND plus experience in electronic engineering including analogue and digital circuit design; experience in microprocessor systems an advantage; ability to work at sea, occasionally, in research vessels and small boats an advantage.

Salary (under review): Scientific Officer to £2,839 to £4,415 or, for candidates with at least two years' postgraduate experience, Higher Scientific Officer to £4,101 to £5,448. Starting salary may be above the minimum.

Staff of the Council are not Civil Servants but pay and conditions are similar to those of the Civil Service, including a non-contributory pension scheme.

For further particulars and application form, please write, quoting Post No. 931, to The Director, Institute for Marine Environmental Research, Prospect Place, The Hoe, Plymouth PL1 3DH. 940(A)

UNIVERSITY OF  
NOTTINGHAM  
School of Agriculture  
SUTTON BONINGTON,  
LOUGHBOROUGH  
DEPARTMENT OF PHYSIOLOGY  
AND ENVIRONMENTAL STUDIES

Applications are invited for the following post which exists within the Department.

**TECHNICIAN GRADE 5—  
ELECTRONICS**

The Technician will be responsible for the design and construction of electronic equipment used in the Environmental Physics section of the Department; and for the routine maintenance and repair of standard equipment in the Department as a whole. Candidates should possess O.N.C., O.N.D., or other recognised equivalent qualifications and appropriate experience is essential.

Salary on scale £3,474 to £4,056 per annum.

Write to the Secretary at the School for an application form quoting Post Ref: 79/10. 929(A)

UNIVERSITY OF  
LIVERPOOL  
DEPARTMENT OF BIOCHEMISTRY  
**RESEARCH ASSISTANT/  
SENIOR  
RESEARCH ASSISTANT**  
Affinity Chromatography

Applications are invited from chemists or biochemists for the above post in a multidisciplinary group working on the principles and applications of affinity techniques. The salary will be within the range £3,689 to £4,776 per annum depending on age and experience. The post is tenable for one year from October 1, 1979. Informal enquiries may be made to Dr. P. D. G. Dean, Tel: 051-707-6022, Ext. 3166.

Applications, together with the names of two referees, should be received not later than June 7, 1979, to The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/600/N. 892(A)

**UNIVERSITY COLLEGE  
DUBLIN  
DEPARTMENT OF ZOOLOGY  
SESSION 1979/80**

A vacancy has arisen for a staff member in the Department of Zoology for the 1979/80 Session. The appointment will be made at the level of either Assistant Lecturer or College Lecturer. Applicants should have teaching, practical and research experience. Preference will be given to candidates with teaching and practical experience in The Invertebrate Phyla (1st Year); Insecta, Reptilia, Aves and Limnology (2nd Year); Animal Behaviour (Honours Level); and also with research experience in Limnology.

This appointment is for one year, from October 1, 1979 to September 30, 1980.

The current salary scales are:

Assistant Lecturer: £4,210 to £6,875 per annum

College Lecturer: £6,610 to £8,486 per annum

Entry point on the relevant scale will be in accordance with qualifications and experience. There is a non-contributory pension scheme.

Prior to application, further information (including application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries 693244, ext. 431.

The latest date for receipt of completed applications is Friday, June 8, 1979. W128(A)

**UNIVERSITY OF GLASGOW  
DEPARTMENT OF  
BIOCHEMISTRY  
POSTDOCTORAL FELLOW**

There is a vacancy for a Postdoctoral Fellow to work in a Research Group in this department in association with the Department of Medical Cardiology, investigating the fundamental questions about the structure of myocardial cells, mechanisms of myofibrillar assembly and degradation, metabolic regulation and the molecular details of drug interactions.

Salary will be on range 1A of the scales for Research and Analogous Staff (£3,883 to £6,555, under review).

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to Dr J. Dow, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 4455M. 871(A)

**BEDFORD COLLEGE  
(University of London)  
ELECTRON MICROSCOPY  
TECHNICIAN**

Technician Grade 7

required from September 1, 1979, to take overall responsibility for the supervision of, and the provision of a technical service from, the College's Electron Microscope Unit. Applicants must be highly skilled in all techniques related to the electron microscope investigation of biological material and in the maintenance of electron microscopes and associated ancillary equipment.

Gross salary within the range £5,162 to £5,735 per annum. Annual season ticket loan scheme.

Application forms from Senior Assistant Secretary (Personnel), Bedford College, Regent's Park, London NW1 4NS. Tel: 01-486 4400, ext. 312. 864(A)

**UNIVERSITY COLLEGE  
CARDIFF**

Applications are invited for the post of **LECTURER** in the

**DEPARTMENT OF ZOOLOGY**

Salary range: £3,883 to £7,754 p.a. Appointment will be made towards the lower end of salary scale. Duties to commence October 1979.

Applications (2 copies), together with the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars are available. Closing date June 7, 1979. Reference 1794. 948(A)

**UNIVERSITY OF  
EDINBURGH  
DEPARTMENT OF  
GENETICS  
LECTURER**

The Department of Genetics has a vacancy for a Lecturer. Applications are particularly invited from those with qualifications and research interests in quantitative and/or population genetics, but other applicants may also be considered. The appointment may be taken up on October 1, 1979 or at any time during the following academic year. Salary will be on the scale £4,232 to £8,452 per annum with placing according to qualifications and experience. Superannuation under U.S.S.

Further particulars may be obtained from Professor J. R. S. Fincham, Department of Genetics, West Mains Road, Edinburgh EH9 3JN, and applications, with the names of two referees, should be submitted to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL by June 30, 1979. Please quote reference 1054. 872(A)

**UNIVERSITY OF SURREY  
DEPARTMENT OF HUMAN  
BIOLOGY AND HEALTH  
TECHNICIAN GRADE 3**

We need a Technician to help with the Research and Teaching activities of a vigorous and expanding department. Applicants should have a good practical knowledge of techniques in animal or human physiology, especially modern methods in electronic recording.

Applicants should be suitably qualified and have had several years' laboratory experience.

The department is in a new building in attractive surroundings, adjacent to an historic town with excellent recreational facilities on the campus and in the surrounding area.

Further particulars and application form for the post may be obtained from the Staff Officer, University of Surrey, Guildford, Surrey, GU2 5XH, or telephone Guildford 71281, ext. 452. 934(A)

**NATIONAL INSTITUTE  
FOR RESEARCH IN  
DAIRYING**

The Biochemistry Department requires a biochemist to work on the metabolism of body reserves during growth, pregnancy and lactation in ruminants. The work involves a study of protein and lipid metabolism in vitro of muscle and other organs taken from animals in different physiological states.

Candidates should have a first or upper second class Honours degree in biochemistry or physiology.

Appointment will be as Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) according to experience. At least two years' relevant postgraduate research or other approved experience is required for appointment as HSO.

Further details and application forms are obtainable from the Secretary, NIRD, Shinfield, Reading RG2 9AT. Please quote reference 79/18. 795(A)

**QUEEN MARY COLLEGE  
University of London  
APPLIED MATHEMATICS  
DEPARTMENT  
Applications are invited for  
appointment as  
POSTDOCTORAL  
RESEARCH ASSISTANT**

to work with Professor I. C. Percival on an S.R.C.-supported project: Hamiltonian Dynamics of Systems with a finite number of degrees of freedom. Appointment for 2 years from October 1.

Initial salary in range £4,835 to £5,412 per annum (including London Allowance).

Please apply by letter, giving age, qualifications, experience and names of 2 referees, to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 862(A)

# MRC

**Medical Research Council**

**M.R.C. CLINICAL RESEARCH CENTRE  
(NORTHWICK PARK HOSPITAL)  
Watford Road, Harrow, Middx. HA1 3UJ**

**SCIENTIFIC OFFICER**

required to work on primate models of psychiatric disease, including particularly schizophrenia. Applicants must have experience of behavioural work with primates, and some knowledge of neuropharmacology. They should also have an interest in the possible role of neurotropic viruses in the causation of psychiatric and neurological disease.

Potential applicants are invited to visit informally the C.R.C. and to discuss their research ideas with Dr T. Crow (Tel. No. 01-864 5311 Ext. 2754).

This is a limited term appointment for five years. Salary within the range £5,631 to £8,256 including L.A.

Application form and further details from Mrs J. Tucker-Bull (Ext. 2685). Quoting Ref. 125/1/A38. Closing date June 16, 887(A)

**GUY'S HOSPITAL  
MEDICAL SCHOOL  
GRADUATE  
RESEARCH ASSISTANT**

required for three years to work with Dr. D. C. Watts in the Biochemistry and Chemistry Department on an investigation into the biochemistry of the subunit interactions of the phosphagen kinases, supported on a grant from the Science Research Council. Salary on scale £3,716 to £3,988 to £4,262 plus £502 London Allowance. Applicants, who will be expected to register for a Ph.D. degree, should have a good honours degree with some knowledge of enzyme chemistry and, preferably, an enthusiasm for marine biology.

Apply in writing, with full curriculum vitae, to Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. B.C.1. 883(A)

**GEOCHRONOLOGIST**

A Geochronology Laboratory is to be established at the University of Regina in the Department of Geology. The successful applicant will be required to design, set-up and operate a solid source mass spectrometry laboratory specialising in uranium-lead and zircon dating methods. The position will be of particular interest to persons with a strong physics background. A knowledge of solid state electronics, minicomputers and data handling. The position, which does not require any teaching or administrative duties, will commence as soon as a suitable candidate is found. Salary will be commensurate with qualifications and experience. Applications, which must indicate availability and salary expected, should be forwarded, along with three letters of reference, to Dr G. R. Parslow, Department of Geology, University of Regina, Regina, Saskatchewan, S4S 0A2, Canada (PRIOR TO JUNE 30, 1979). W121(A)

**THE UNIVERSITY OF  
MANCHESTER  
ELECTRON MICROSCOPE  
TECHNICIAN  
DEPARTMENT OF MEDICAL  
BIOCHEMISTRY**

required to work with a small research team led by Professor Scott on structure and function of connective tissue. In addition to experience of electron microscopy, an interest in biochemistry is desirable, and candidates should be qualified to at least O.N.C. level.

Commencing salary up to £3,315 per annum.

Applications should be sent to Professor J. E. Scott, Department of Medical Biochemistry, Stopford Building, The University, Manchester M13 9PT. 944(A)

**UNIVERSITY OF HULL  
DEPARTMENT OF GEOLOGY  
POSTGRADUATE  
RESEARCH ASSISTANT**

Applications are invited from graduates, or from those expecting to graduate this year, for the position of research assistant on a three-year N.E.R.C.-funded project on diagenesis and patterns of cementation in sandstones. The project commences on September 1, 1979.

Salary will be on the scale £3,684 to £5,321 per annum.

The person appointed may register for a higher degree, if suitably qualified.

Applicants with relevant qualifications in the geological sciences should write to Dr B. Waugh, Department of Geology, University of Hull, Hull HU6 7RX, before June 8, 1979, and should include a full curriculum vitae and the names of two referees. 879(A)

**UNIVERSITY OF GLASGOW  
DEPARTMENT OF BIOCHEMISTRY  
POSTDOCTORAL FELLOW**

There is a vacancy for a Postdoctoral Fellow to work in a Research Group in this department in association with the Department of Medical Cardiology, investigating the fundamental questions about the structure of myocardial cells, mechanisms of myofibrillar assembly and degradation, metabolic regulation and the molecular details of drug interactions.

Salary will be on range 1A of the scales for Research and Analogous Staff (£3,883 to £6,555, under review).

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to Dr J. Dow, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 4455. 943(A)

**MEMORIAL UNIVERSITY  
OF NEWFOUNDLAND  
Canada  
ASSISTANT PROFESSOR  
(Research)**

required to join a project on the molecular comparison of genes specifying isofunctional catabolic enzymes in plasmids.

A candidate with a Ph.D. is required, and someone with experience of work with DNA and restriction enzymes is preferred. Contractual appointment for two years, in the first instance, on a salary scale commencing at \$16,950 per annum.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr E. A. Barnsley, Department of Biochemistry, Science Building, Memorial University of Newfoundland, St. John's, Newfoundland, Canada A1B 3X9. 914(A)

## Smith Kline - RIT

a SmithKline company

For our Immunobiology Department we wish to engage at short notice

### A VIROLOGIST

with several years' experience in the field of virology (technique of tissue culture, virus culture and of virological diagnosis). He (she) will be engaged in research and development in the field of virus vaccines.

The applicant should speak English fluently and must at least have a fair knowledge of French.

He (she) is preferably between 30 and 35 years old.

Should you be interested in this job, send your application with curriculum vitae to our Personnel Department, 13 rue du Tilleul, 1320 Genval, Belgium. W131(A)

### MEDICAL, DENTAL AND VETERINARY PHYSIOLOGISTS

The Department of Physiology at Tufts University Schools of Medicine, Dental Medicine and Veterinary Medicine is seeking physiologists for tenure-track positions at the assistant and associate professor levels. Of particular interest are persons with strong research in cell physiology and teaching ability in the areas of organ, comparative and avian physiology. The department is committed to developing research programs relating to the interests of the three schools so that persons with the M.D., D.M.D., D.V.M. and/or Ph.D. degrees are encouraged to apply. Applicants should send a letter describing their research and teaching interests, a curriculum vitae with publication list and the names of three references to: Dr. Geoffrey W. G. Sharp, Department of Physiology, Tufts University Schools of Medicine, Dental Medicine and Veterinary Medicine, 136 Harrison Avenue, Boston, Massachusetts 02111.

Tufts University is an Equal Opportunity/Affirmative Action Employer. W123(A)

### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GEOGRAPHY RESEARCH FELLOW AND RESEARCH ASSOCIATES (2)

Leverhulme Trust Research Project on Viking Settlement, climate and environmental change around the North Atlantic.

Applications are invited for three research appointments in connection with the above 3-year project.

#### 1. RESEARCH FELLOW (ARCHAEOLOGIST)

Preference will be given to postdoctoral candidates with a working knowledge of Viking settlement, particularly in Iceland, and experience of archaeological and/or geographical fieldwork techniques. Ability to use published Icelandic data would be an advantage. Salary on the scale £4,232 to £7,145 per annum, plus superannuation. Maximum starting salary will be £4,776. Post tenable from July 1, 1979.

#### 2. RESEARCH ASSOCIATES

Candidates should have a good honours degree with preferred specialism in botany or entomology and a general interest in archaeology. Salary on the scale £3,775 to £5,488 per annum, plus superannuation. Maximum starting salary will be £4,333. Post tenable from October 1, 1979.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees, should be sent by Friday, June 8, 1979. Please quote reference NH6. 925(A)

### UNIVERSITY OF BATH SCHOOL OF MATERIALS SCIENCE LECTURER in MATERIALS SCIENCE

The School offers an honours degree in Materials Science and has extensive teaching commitments in Engineering Schools of the University. The lecturer is required to share in this teaching programme and the ideal candidate would be one who has experience in the field of selection and evaluation of engineering materials and is familiar with engineering design procedures. A strong professional or academic record would be essential and the successful candidate would be expected to contribute actively to the School's research activities.

Application forms and further particulars available from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference 79/104/N. Closing date for applications: June 18, 1979. 885(A)

### UNIVERSITY OF THE WEST INDIES—JAMAICA Applications are invited for the post of LECTURER/ ASSISTANT LECTURER in the DEPARTMENT OF BOTANY

Preference will be given to applicants who possess a first degree with majors in Botany and hold postgraduate qualifications or have interest and teaching experience in Plant Ecology and Taxonomy of Seed Plants. The appointee will be required to take up duties as soon as possible.

Salary scale (under review): Lecturer, J\$8,913 to J\$13,917 per annum; Assistant Lecturer, J\$7,236 to J\$7,926 per annum (£1=J\$3.60). Family passages; F.S.S.U.; Study and Travel Grant; Unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary is payable.

Detailed applications (three copies) with curriculum vitae and naming 3 referees should be sent direct as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 857(A)

TECHNICIAN Grade 5, with knowledge of Cytology required to assist in both the research and undergraduate teaching laboratories in the Department of Botany and Microbiology. It is essential for applicants to have a sound knowledge of Cytological Techniques. Salary according to experience in range £3,998 to £4,580 inc. of London Weighting. Application form and further details from Personnel Officer (Technical Staff CD13), University College London, Gower St., WC1E 6BT. 913(A)

### UNIVERSITY OF BASEL DEPARTMENT OF STRUCTURAL BIOLOGY POSTDOCTORAL POSITION

Development of new *ab initio* methods for the theoretical study of large molecules and their application to problems in Pharmacology. Experience with Quantum Chemical methods and programming techniques desirable. Send resume and names of two referees to Dr E. L. Mehler, Department of Structural Biology, Biocenter, The University of Basle, CH-4056 Basle, Switzerland. W127(A)

### UNIVERSITY OF PAPUA NEW GUINEA Applications are invited for the post of SENIOR TECHNICIAN (ELECTRONICS) in the DEPARTMENT OF PHYSICS

The appointee will be expected to perform the following duties: Take charge of a small, modern and well equipped electronics workshop; to provide on-the-job training to National Technicians; maintain and calibrate a wide variety of electronic instrumentation; design and develop a digital and analogue instrumentation for teaching and research. Applicants should hold a Higher National Certificate or equivalent qualification in Electronic Engineering and have several years appropriate experience. Appointment will be at the level of Senior Technical Officer Grade 2.

Salary: K10,165 per annum (£1 sterling=K1.49). Family passages; baggage allowance; gratuity; various generous allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Secretary, Box 4820, University P.O., Papua New Guinea, by June 29, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 861(A)

### UNIVERSITY OF OXFORD NUFFIELD INSTITUTE FOR MEDICAL RESEARCH

A post is available to work on some aspect of the physiology of the embryo, fetus or newborn. Preference may be given to an applicant with interest in embryology or neurophysiology. The appointment, tenable from October 1, 1979, is for three years initially, and may be extended for a further two years (maximum). Salary on University Research Staff Scale II (£6,080 to £7,754 per annum) or IIX (£6,317 to £8,257 per annum).

Application or enquiries, with curriculum vitae and names of three referees to:

Professor G. S. Dawes,  
Nuffield Institute for  
Medical Research,  
Headley Way,  
Headington,  
Oxford OX3 9DS. 902(A)

### UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF GENETICS POSTDOCTORAL RESEARCH ASSOCIATE

Do operons exist in eukaryotic organisms? Applications are invited for the above post in an S.R.C.-financed study of gene clusters and their control using the fungus *Aspergillus nidulans*. Starting date as soon as possible and not later than November 1, 1979. Tenable for three years. Biochemical background an advantage. Starting salary within Range 1A Research scale (4,232 to £4,776).

Applications with names and addresses of two referees to Dr H. N. Arst, Department of Genetics, Ridley Building, The University, Newcastle upon Tyne NE1 7RU. 952(A)

### UNIVERSITY OF ST. ANDREWS DEPARTMENT OF PSYCHOLOGY Applications are invited for TWO LECTURESHIPS

in the Department of Psychology, tenable from September/October 1979. For one post candidates should have advanced training and experience to qualify them for an appointment in any area of Human Psychology, and for other a background in Social Psychology, Sociology, or allied disciplines.

Salary at appropriate point on scale £4,232 to £8,452 (under review), starting salary probably not above £6,108, plus F.S.S.U./U.S.S.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by June 30, 1979, with the Establishments Officer, The University, College Gate, St. Andrews, Fife, from whom further particulars may be obtained. 972(A)

### UNIVERSITY OF BRISTOL BONE BIOMECHANICS A RESEARCH ASSISTANT

is required to participate in a project financed by the M.R.C. to investigate the effect of mechanical function on bone remodelling, particularly in relation to senile and disuse osteoporosis. The experiments will involve instrumentation of bones in vivo.

This is a postdoctoral appointment but applicants with other suitable experience will be considered.

Salary in the range 1A £4,505 (£4,776 to £5,041) p.a. (under review).

Applications, including a curriculum vitae and the names of two referees, should be sent before June 11 to Dr L. E. Lanyon, Department of Anatomy, University of Bristol, Park Row, Bristol BS1 5LS, U.K. 947(A)

### UNIVERSITY OF NEWCASTLE UPON TYNE DEMONSTRATORSHIP IN ORGANIC CHEMISTRY

Applications are invited for the above post in the Department of Organic Chemistry, tenable from September 1, 1979, or by arrangement. Applicants should have, or expect to have, a Ph.D. in Organic Chemistry. The successful applicant will be expected to assist with both undergraduate and postgraduate teaching and to carry out research of his or her own choice in an area of Organic Chemistry.

The appointment is for three years with salary on the Grade 1B (bar) scale: £3,384 to £4,882 (under review) according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Two copies of applications, together with the names and addresses of three referees, should be sent to Professor Sir James Baddiley, FRS, Microbiological Chemistry Research Laboratory, The University, Newcastle upon Tyne NE1 7RU. 875(A)

### POSTDOCTORAL RESEARCH ON HORMONE RECEPTORS

Areas of interest include interaction of glucagon with membrane receptors and the role of lipids as well as the development of a glucagon antagonist. Candidate should have experience with biological membranes, endocrinology or lipid or protein chemistry.

Applications with full curriculum vitae and names of two references to:

Dr R. M. Epand  
Department of Biochemistry  
McMaster University  
1200 Main Street West  
Hamilton, Ontario  
L8S 4J9, Canada. W115(A)

**THE  
UNIVERSITY COLLEGE  
OF WALES  
ABERYSTWYTH**

**DEPARTMENT OF GEOLOGY**  
Applications are invited for the post of

**PART-TIME  
DEMONSTRATOR**

tenable for an initial period of two years from October 1, 1979. A good Honours Degree in Geology is required and the post offers the opportunity to pursue research, which may lead to a higher Degree. Salary on commencement £3,000 per annum (under review) rising to £3,250 after twelve months.

Application forms and further particulars are obtainable from The Registrar, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX, to whom completed forms should be submitted no later than June 4, 1979. 908(A)

**UNIVERSITY OF  
CAMBRIDGE**

Department of Biochemistry  
Applications are invited for a

**POSTDOCTORAL RESEARCH  
ASSISTANT (Range 1A)**

to work with Professor D. H. Northcote, F.R.S. on a project funded for three years by the Science Research Council. Whole plants and plant tissue cultures will be used to investigate the key metabolic step in polysaccharide synthesis during the induced and *in vivo* differentiation of plant tissue. The date of commencement for this post is October 1, 1979.

Applicants should send a curriculum vitae and names of two referees to: Professor D. H. Northcote, F.R.S. Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge CB1 1QW. 956(A)

**KINGSTON POLYTECHNIC  
SCHOOL OF CHEMICAL AND  
PHYSICAL SCIENCES  
SENIOR TECHNICIAN**

To be responsible for a Life Science laboratory, which is used for undergraduate teaching, research and project work. Duties include microbiology, plant studies and tissue culture work plus experimental development and investigational work. An important post requiring someone with initiative and enthusiasm. T3/4 grade up to £4,953 inclusive.

**TECHNICIAN**

To be responsible for a postgraduate research laboratory. Interesting post with wide variety of duties. Applicants will be expected to have at least 'A' level chemistry and be able to assist research students and staff. Other duties include maintenance and servicing of laboratory equipment and other general duties. T2 grade up to £3,972 inclusive.

Details and application forms from Assistant Registrar (personnel), Kingston upon Thames KT1 2EE. Tel: 01-549 1366. 975(A)

**EDITORIAL RESEARCH ASSISTANT** required to work with Professor G. Burnstock in the Department of Anatomy. Experience is required in biomedical research together with ability to edit scientific material. The position would also involve helping to co-ordinate the research activities of a group of research workers including postgraduates and postdoctorals from overseas. Salary range: £5,074 to £6,368 per annum plus £502 London Allowance. Applications, together with names of two referees and full curriculum vitae to Assistant Secretary (Personnel), University College London, Gower St., London WC1E 6BT. 906(A)

**UNIVERSITY OF  
SIERRA LEONE  
NJALA UNIVERSITY  
COLLEGE**

Applications are invited for two **LECTURERS** in the Department of Environmental Studies and Geography in the Faculty of Education.

**LECTURER IN  
CLIMATOLOGY**

Candidates should have at least a second degree with specialisation in Climatology. The appointee will teach undergraduate courses in Climatology, agro-climatology, and participate in research on local environments. An interest in biogeography, tropical hydrology and moisture problems is an advantage.

**LECTURER IN REGIONAL  
SCIENCE AND  
QUANTITATIVE METHODS**

Candidates should have at least a second degree with bias for spatial analysis. The appointee should be able to teach basic concepts of quantitative methods to second and third year students and act as supervisor for final year students preparing dissertations.

Candidates with an option for project evaluation, planning, locational analysis and rural development in third World Environments are preferred. Salary scale: Lecturer: Le4,488 to Le6,897 per annum. (£1 Sterling = Le2.21). Family passages; University Superannuation or contract terms; annual leave; car loan negotiated. Part-furnished accommodation at reasonable rental; various allowances. Detailed applications (copies) with curriculum vitae and naming three referees, should be sent direct to the Secretary, University Sierra Leone, Private Mail Bag, Freetown, Sierra Leone by July 11, 1979. Applicants resident in the UK should also send one copy of their application to the Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 966(A)

**UNIVERSITY COLLEGE OF  
SWAZILAND**

Applications are invited for the post of

**LECTURER**

in the Department of Agricultural Economics. Candidates should possess an M.Sc. in Agricultural Economics with a major in Farm Management. Experience in Farm Management and/or in lecturing in this subject would be an additional recommendation. The appointee will lecture in Farm Accounts, Farm Management and in other topics relative to Agricultural Economics, as required. Salary scales: Lecturer I: E5,940 to E7,860 per annum. (£1 sterling = E1.75). The British Government may supplement salary by E1,650 to E2,184 per annum (sterling) for married appointee or E408 to E960 per annum (sterling) for single appointee (reviewed annually and normally free from tax) and provide children education allowances and holiday visit passages. Family passages; 2 to 4 year contracts; if appointment for limited period 25 per cent gratuity in lieu of superannuation for first 2 years and 27½ per cent for second 2 years; 10 per cent inducement allowance payable for those not obtaining supplementation from other sources; education allowance; reasonable rented accommodation; biennial leave. Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University College of Swaziland, Private Bag, Kwaluseni, Swaziland by July 11, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address. 965(A)

**UNIVERSITY OF  
STIRLING  
DEPARTMENT OF  
BIOCHEMISTRY**

**TECHNICIAN GRADE 4**

Applications are invited for the above post. Previous experience in a Biochemistry Laboratory or related science laboratory essential. The main duties of the successful applicant will be to prepare practical classes and also assist in research in the department. Minimum of O.N.C. or equivalent qualification essential. Salary scale £3,222 to £3,708.

Application forms are available from the Establishments Office, University of Stirling, Stirling FK9 4LA. Tel: Stirling 3171. Ext: 2314. Closing date: June 4, 1979. 938(A)

**Academic Department  
of Child Health**

**The Charles Hayward  
Research Building  
Queen Elizabeth**

**Hospital for Children  
Hackney Road, London E2 8PS  
A JUNIOR  
MEDICAL LABORATORY  
SCIENTIFIC OFFICER B**

is required to carry out, under supervision, a research project investigating lymphoid cells in the small intestinal mucosa. The research will involve the application of immunological and cytological techniques to intestinal biopsy samples from children with gastrointestinal problems. A knowledge of immunology is desirable but not essential. Preferred qualifications—a Degree or H.N.C. in Biological Science. Minimum qualifications: two Science G.C.E. 'A' levels. Salary (at age 21 or over) £3,243 per annum, including London Weighting.

Application forms and further information can be obtained from Dr J. A. Walker-Smith. 904(A)

**UNIVERSITY OF OXFORD  
RESEARCH ASSOCIATE  
IN NEUROPHYSIOLOGY**

Applications are invited for this post to work on the activity of single neurones in visual, limbic, and motor areas of the primate brain. The post is appropriate for a postdoctoral scientist with experience in neurophysiology.

The salary is on the R.S. 1A salary scale, £3,883 to £6,555 (under review). Applications in writing to Dr E. T. Rolls, Department of Experimental Psychology, South Parks Road, Oxford OX1 3UD, England. 903(A)

**UNIVERSITY OF  
MANCHESTER  
RESEARCH ASSISTANT  
in the  
DEPARTMENT OF  
CHILD HEALTH**

Graduate with biological qualifications required to help with investigations into growth and development and its control. Salary range £3,689 to £5,321 per annum (£3,775 to £5,488 per annum from October, 1979). Applications with full personal details to Professor J. Dobbing, The Medical School, Oxford Road, Manchester M13 9PT. 915(A)

**POSTDOCTORAL POSITION** available 2 to 3 years for soil microbiologist interested in characterising tropical Rhizobia. Collaborative project with IITA Nigeria. Objective to increase nitrogen fixation by grain legumes in tropical farming systems. Send curriculum vitae and three references to Dr Allan Eaglesham, Boyce Thompson Institute at Cornell University, Ithaca NY 14853 USA. W117(A)

**ASSOCIATESHIPS**

**HERIOT-WATT  
UNIVERSITY**

**Riccarton  
DEPARTMENT OF CHEMISTRY  
S.R.C. POSTDOCTORAL  
RESEARCH  
ASSOCIATESHIP**

Applications are invited for the above post to study stereochemical aspects of some biosynthetic processes involving amino-acids. Applicants should be experienced synthetic organic chemists, with a strong interest in biological chemistry. The post is available for two years from October 1, 1979, but a later starting date would also be possible. The starting salary would be expected to be on the scale £4,333 to £4,910 per annum (subject to further revision).

Applications, giving the names of two referees, should be sent to Dr R. H. Wightman, Department of Chemistry, Heriot-Watt University, Edinburgh EH14 4AS, from whom further details can be obtained. 954(O)

**CONFERENCES**

**CALL FOR ABSTRACTS  
BIOPHYSICAL DISCUSSIONS  
Second Discussion—May 1980  
PROTEINS AND  
NUCLEOPROTEINS:  
STRUCTURE, DYNAMICS  
AND ASSEMBLY**

The Biophysical Society will hold its 2nd Biophysical Discussion at Airlee House, Airlee, Virginia (near Washington, D.C.) on May 18-21, 1980. This Discussion will consider recent advances in understanding the principles of macromolecular structure and dynamics. Sessions will be devoted to: elucidation of structure by diffraction and spectroscopic methods; nature of forces stabilizing macromolecular structure; fluctuations in macromolecular structures; and mechanisms of folding and assembly. Experimental systems to be discussed include proteins, viruses, and organelles involving protein-nucleic acid interactions.

Prior to the meeting, all participants will receive a study book containing the full Discussion papers and poster abstracts. There will be no formal presentation of papers at the meeting, only a five-minute reminder followed by open discussion. A \$175 fee will cover registration, three days' room and board, the study book, and the final proceedings volume.

Papers submitted for the Organizing Committee's consideration are due as follows:

July 16, 1979—Preliminary abstracts (<300 words, to be reviewed and selected by August 1st)

December 1, 1979—Complete manuscripts (to be refereed and selected by mid-January)

The full edited proceedings of ca. 500 pp, will be published in hardback by Rockefeller University Press (\$20 prepublication, \$30 after October 1980). Identical text will be received by *Biophysical Journal* subscribers (1980 subscription, 12 issues, \$150). For these publications, remit to Order Service, Rockefeller University Press, P.O. Box 5108, New York, N.Y. 10249, USA.

For further information contact Valerie Parsegian, Executive Secretary, Biophysical Discussions, P.O. Box 30239, Bethesda, Maryland 20014, USA. Phone (202) 362-8184. W93(C)

## CONFERENCES—continued

## THREE IMPORTANT CONFERENCES

25 and 26 September 1979

### ADVANCES IN MICROBIOLOGICAL TECHNIQUES Foods, Pharmaceuticals and Cosmetics

In an intensive programme experts from academic and industrial establishments will consider the latest techniques for the identification and enumeration of micro-organisms. There will also be an important session on standards.

3 and 4 October 1979

### PHOTOGRAPHY IN PRACTICE — GETTING SUCCESSFUL RESULTS FROM PHOTOGRAPHIC AND VIDEO TECHNIQUES IN SCIENCE AND TECHNOLOGY

This conference is intended to help the scientist or technologist who is not a professional photographer to use photography as an effect tool and to obtain improved results for visual aids. There will also be review papers on visual psychology and holography.

22 and 23 October 1979

### INDUSTRIAL APPLICATIONS OF ELECTRON MICROSCOPY with particular reference to quality control

In a comprehensive programme acknowledged experts will discuss the practical applications of electron microscopy in a wide range of industrial situations. In addition to examples from specific industries there will be papers on the types of information obtainable with EM.

The venue for all three conferences will be the Sudbury Conference Centre, London EC1 which is near St. Paul's Cathedral.

## ENDOCRINOLOGY '79

16-19 July 1979

Organised by the Endocrinology Unit at the R.P.M.S. and held at the Royal College of Physicians in London

### PROVISIONAL PROGRAMME

MONDAY, JULY 16: A. G. E. Pearce, Peptides of the brain and gut; P. C. Emson, Neurochemical studies on several brain peptides; S. E. Bloom, The endorphins; I. MacIntyre, Inter-relation effects in bone and role in cancer hypercalcaemia.

TUESDAY, JULY 17: G. D. Whedon, Metabolic and endocrine hormone studies in various mammal space flights; W. A. Peck, The cellular basis of osteoporosis; H. W. Boyer, Advances in molecular biology: implications for endocrinology; F. Gautier, Characterisation of porcine parathyroid hormone mRNA, cDNA, and cDNA-pBR322 hybrid plasmids; H. M. Kronenberg, Studies of cloned DNA coding for preproparathyroid hormone R. A. Hallowell, Studies of expression of human growth hormone by *E. coli* K12; H. M. Goodman, The structure and evolution of several mammalian polypeptide hormone genes.

WEDNESDAY, JULY 18: R. J. Vane, Prostacyclin; H. W. Kosterlitz, Enkephalins: receptors, biosynthesis and release; D. Hudson, An investigation of enkephalin-receptor interaction employing isosterically modified analogues; J. Alumets, Enkephalin in intrinsic nerves and endocrine cells of the gut and in two rectal carcinoids; A. Dell, Neuropeptides: high resolution purification procedures and their application to the study of new opiate peptides and opiate peptide precursors; B. M. Austen: Pituitary granules contain a protease specific for consecutive basic residues; T. M. Badger, The effects of chronic treatment with LHRH and a LHRH agonist (D-Trp<sup>6</sup>-Pro<sup>9</sup>-NH<sub>2</sub>-LRF) on the pituitary-gonadal regulation of LH and FSH secretion; P. Bernd, Serotonin binding protein—localisation in parafollicular cells of the sheep thyroid; L. Orci, Studies in peptide hormone secretion.

THURSDAY, JULY 19: L. J. Deftos, Calcitonin: current aspects of physiology and pathophysiology; C. Nagant de Deuxchaisnes, Studies in osteomalacia; A. W. Norman, Recent advances in Vitamin D metabolism; B. E. C. Nordin, Role of Vitamin D and its metabolites in malabsorption of calcium in osteoporosis.

A. Canigga, V. S. Fang, M. C. Sheppard, F. G. Hawkins-Carranza, P. J. Meunier, R. Ziegler, M. F. Holick, O. H. Sørensen, J. A. Kanis, G. Mazzuoli, J. C. Ghazarian, J. H. Cort, C. Milet.

Details: P. Lindsay, Endocrinology '79  
R.P.M.S., Du Cane Road  
LONDON W12 0HS. Tel: 01-743 2030, ext. 457

782(C)

## COURSES

### UNIVERSITY OF SOUTHAMPTON M.Sc./Diploma in Biological and Chemical Methods in Pest Control

This one-year course, which commences in October, is open to graduates in Biology, Chemistry, Biochemistry, Agriculture or any related subject. It provides instruction in modern techniques and methods used in pest management, and is particularly suitable for graduates in Biology or Chemistry who wish to become proficient in relevant aspects of both subjects.

Further information may be obtained from Dr J. W. S. Bradshaw, Department of Biology, Building 3, The University, Southampton SO9 5NH, please quote reference number 1902/R/N 933(D)

## STUDENTSHIPS

### UNIVERSITY OF LEICESTER

#### RESEARCH STUDENTSHIP

available in the GENETICS DEPARTMENT for work leading to a Ph.D. in one of the following areas: biochemical and developmental genetics of mouse or *Physarum*; population genetics of small mammals; cell division, surface biogenesis and DNA replication (including plasmids) in bacteria; molecular structure of human and rabbit haemoglobin genes.

Further details and applications as soon as possible to Dr I. B. Holland. Applicants should have or hope to have at least a 2(i) degree in a biological science. 939(F)

### UNIVERSITY OF LIVERPOOL

#### DEPARTMENT OF IMMUNOLOGY UNIVERSITY

#### POSTGRADUATE

#### RESEARCH STUDENTSHIP

Applications are invited from good honours graduates in a biological science who expect to graduate this year for a University Postgraduate Research Studentship to investigate immunological resistance to tumour growth induced by pregnancy in experimental animals.

The studentship is tenable for three years, subject to satisfactory progress, commencing in October 1979 and the successful candidate will be registered for the degree of Ph.D.

Applications, together with the names of two referees, should be received as soon as possible, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/613/N. 950(F)

### UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY S.R.C. and

#### S.R.C./S.S.R.C. RESEARCH STUDENTSHIPS

Applications are invited for one S.R.C. Research Studentship and two S.R.C./S.S.R.C. Studentships from October 1979. The S.R.C. award may be used to study any area of Botany. The S.R.C./S.S.R.C. awards will normally involve a more applied project supervised jointly by the Botany and Industrial Studies Departments.

Applicants must possess or expect to gain a good honours degree in a biological science. Areas of research interest should be stated in the application.

Applications, including details of academic experience and the names of two referees, should be received not later than June 8, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/606/N. 889(F)

### UNIVERSITY OF NOTTINGHAM

#### FACULTY OF AGRICULTURAL SCIENCE S.R.C. (C.A.S.E.) RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship to investigate the relationship between the structure and the texture and appearance of a new type of food gelling agent. The project is in conjunction with a leading food manufacturer and will be aimed at obtaining increased understanding of this novel material. The successful candidate will be required to adopt a multidisciplinary approach and work in close collaboration with the Company concerned.

The successful applicant will be expected to register for the degree of Ph.D. Candidates holding a degree in Chemistry, Physics, Food Science or Biochemistry should apply to Dr J. R. Mitchell, Department of Applied Biochemistry and Nutrition, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. LE12 5RD, enclosing a brief curriculum vitae. 927(F)

### UNIVERSITY OF LONDON KING'S COLLEGE

#### ZOOLOGY DEPARTMENT

Applications are invited for

#### TWO S.R.C. STUDENTSHIPS

leading to a Ph.D. degree, from applicants who have, or expect to obtain this year, a first or upper second class degree in Zoology or Biology.

1. Q.U.O.T.A. Award, to undertake research in one of the following fields:—

(a) 'Relationship of low molecular weight RNAs to gene activity in *Amoeba*'. Supervisor: Dr S. E. Hawkins;

(b) 'Structural and physiological basis of autotomy in starfish'. Supervisor: Dr R. H. Emson;

(c) 'Instar development in 1-, 2- and 3-host ticks'. Supervisor: Professor Don R. Arthur.

2. C.A.S.E. Award, jointly with the Pest Infestation Control Laboratory of the Ministry of Agriculture, Fisheries and Food, for an investigation of the behavioural and physiological activity of odorous (pheromonal) compounds in the rat. Supervisor: Dr D. M. Stoddart.

Application forms and further particulars may be obtained from the Secretary, Zoology Department, King's College, Strand, London WC2R 2LS. 970(F)

### UNIVERSITY OF NOTTINGHAM DEPARTMENT OF THEORETICAL MECHANICS S.R.C.

#### RESEARCH STUDENTSHIPS

The Science Research Council is prepared this year to offer to suitable candidates a limited number of research studentships tenable in the above department. The main research interests in the department are in various aspects of the theoretical mechanics of solids and fluids. One of the awards is a C.A.S.E. award in collaboration with Rolls-Royce Ltd on 'Combustion modelling in reheat systems'. Candidates (including those expecting to graduate this year) should be applied mathematicians, or engineers or scientists with a strong mathematical background. The value and conditions of these awards will be as described in S.R.C. publications. Applications and requests for further details should be made to Professor A. J. M. Spencer as soon as possible. 880(F)

## STUDENTSHIPS—continued

UNIVERSITY OF  
LIVERPOOLDEPARTMENT OF BOTANY  
RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship tenable from October 1979 to study Biochemical Properties of Protoplasts from *Aspergillus nidulans*.

Applicants must possess or expect to gain a good honours degree in a biological science or biochemistry, with experience in Mycology, Fungal Physiology or Microbiology.

Applications, including details of academic experience and the names of two referees, should be received not later than June 8, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/605/N. 890(F)

UNIVERSITY OF  
LIVERPOOLDEPARTMENT OF BOTANY  
N.E.R.C.

## RESEARCH STUDENTSHIPS

Applications are invited for two Research Studentships tenable from October 1979 to study (a) Plant Community Dynamics of Heathland Colonisation following Severe Disturbance and (b) Translocation and Nutrient Absorption by Rhizomorphs of Basidiomycetes.

Applicants must possess or expect to gain a good honours degree in a biological science, with experience in Ecology, Mycology or Plant Physiology.

Applications, including details of academic experience and the names of two referees, should be received not later than June 8, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/604/N. 891(F)

UNIVERSITY OF  
SOUTHAMPTON

## DEPARTMENT OF CHEMISTRY

Applications are invited for the following CASE Studentships:

- (1) Synthesis of Antibiotics (Professor R. C. Cookson with Glaxo-Allenburys Research Ltd).
- (2) Synthesis of Bridged Heterocyclic Annulenes and Diazepines (Dr J. M. Mellor with Roussel Labs Ltd).
- (3) Organometallic Complex-Catalysed Reactions of Isoprene (Professor R. Baker with Bush, Boake, Allen Ltd).
- (4) Biologically Active Compounds in Insect Tissue (Professor R. Baker and Dr J. W. S. Bradshaw with May & Baker Ltd).

The successful candidates will be expected to register for a higher degree.

Applications, including the names of two referees should be sent to the appropriate academic supervisor at the Chemistry Department, The University, Southampton SO9 5NH. 932(F)

S.R.C./C.A.S.E. RESEARCH  
STUDENTSHIPDEPARTMENT OF PLANT  
BIOLOGYUNIVERSITY OF  
NEWCASTLE UPON TYNE

Applications invited from persons with a first or upper second class honours degree, for a C.A.S.E. studentship in plant biochemistry. The project deals with photorespiration and is entitled "Metabolic consequences of excessive ammonia production in leaves". Dr A. J. Keys of Rothamsted Experimental Station will be co-supervisor.

Details available from Dr C. V. Givan, Department of Plant Biology, The University, Newcastle upon Tyne, NE1 7RU, to whom applications should be sent with names of two referees. 963(F)

UNIVERSITY OF SURREY  
DEPARTMENT OF  
BIOCHEMISTRY  
S.R.C. C.A.S.E.  
STUDENTSHIP

Applications are invited for a C.A.S.E. Studentship financed by S.R.C. in collaboration with Shell Toxicology Laboratory, Sittingbourne, Kent, tenable for three years and for work on

Molecular studies of the fidelity of DNA repair

Applicants must have or expect to obtain upper second or first class honours in Biochemistry or a related subject.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Dr L. J. King before June 25, 1979.

Department of Biochemistry,  
University of Surrey,  
Guildford GU2 5XH.  
Tel: Guildford (0483) 71281, Ext. 499. 937(F)

UNIVERSITY OF  
ABERDEENDEPARTMENT OF  
PHYSIOLOGY

## S.R.C.

## RESEARCH STUDENTSHIP

Applications are invited from graduates, or those expecting to graduate this summer, for a S.R.C. Research Studentship. A variety of research topics are available in such areas as endocrinology, neurophysiology, hyperbaric physiology, electrophysiology of nerve and muscle, haemostatic mechanisms, respiratory physiology and muscle physiology.

Details of academic record, names of two referees and requests for further information should be sent to the Head of the Department of Physiology, University of Aberdeen, Marischal College, Broad Street, Aberdeen AB9 1AS. 901(F)

OXFORD POLYTECHNIC  
DEPARTMENT OF BIOLOGY

## S.R.C.

## RESEARCH STUDENTSHIP

Applications are invited for Science Research Council Studentships in the Department of Biology for three years from October 1, 1979.

The main research interests in the Department are in the areas of Biochemistry, Animal Physiology, Insect Physiology and Biochemical Ecology.

Applicants must hold, or expect to hold, a First or Upper Second Honours Degree in an appropriate discipline.

Applications with the names of two referees should be made as soon as possible to

David R. Mobbs,  
Head of Department of Biology,  
Oxford Polytechnic,  
Oxford. OX3 0BP.

from whom further details are available. 882(F)

N.E.R.C., Unit of Invertebrate  
Virology, OxfordN.E.R.C. RESEARCH  
STUDENTSHIP 1979

Applications are invited for a Natural Environment Research Council Studentship to work on the biological and biochemical characterization of small R.N.A. viruses of invertebrates. The Studentship will be tenable for up to three years from October 1979 and the successful applicant will be expected to read for a higher degree. Applicants should have or expect to obtain a first or upper class second degree in a biochemical or biological subject.

Applications should be made to Dr Norman F. Moore, N.E.R.C., Unit of Invertebrate Virology, 5, South Parks Road, Oxford OX1 3UB. 923(F)

LIVERPOOL POLYTECHNIC  
DEPARTMENT OF BIOLOGY

Applications are invited for the following *Research Studentships/Research Assistantships*, tenable for three years, in the Department of Biology. Applicants should hold or expect to obtain a first or upper second class honours degree in an appropriate biological subject. Successful applicants will be required to register for a higher degree with the possibility of this leading to a Ph.D.

1. Ministry of Agriculture, Fisheries and Food Research  
Studentships

## PLANT PATHOLOGY

Supervisor: Dr. T. M. Jeves

"Plant pathogenic *Phytophthora* species in the irrigation water of commercial nurseries."

## 2. Science Research Council C.A.S.E. Studentship

## MICROBIOLOGY-BIOCHEMISTRY

Supervisors: Dr. C. T. Calam and Dr. G. P. Sharples

"The physiology and fine structure of actinomycetes during antibiotic production."

This studentship is held in collaboration with I.C.I. Ltd., Pharmaceutical Division, Manchester.

## 3. Natural Environment Research Council Studentship

One studentship for studies on EITHER

## SOIL ECOLOGY

Supervisor: Dr. M. S. Luxton

"Ecology of the soil mites of coal shale waste heaps."

OR

## POLLUTION ECOLOGY

Supervisors: Dr. I. D. Hodgkinson and Dr. N. W. Lepp

"Studies on trace metal transfer from plants to invertebrate herbivore food chains."

The pollution ecology studentship will form a part of a team programme concerned with various aspects of trace metal pollution studies.

## 4. Science Research Council Studentship

One studentship for studies on one of the following areas:

## GENETICS

Supervisor: Dr. J. P. Margham

"Genetics of either flour beetles of the genus *Tribolium* or the yellow fever mosquito *Aedes aegypti*, with particular reference to insecticide resistance studies."

## DENDROCHRONOLOGY

Supervisor: Dr. M. K. Hughes

"The use of X-ray densitometric and other novel techniques in dating timbers from buildings and archaeological sites."

## AVIAN TAXONOMY

Supervisor: Dr. W. G. Hale

"Variations in egg shell structure in relation to the classification of the Charadriiformes."

## INVERTEBRATE DIGESTIVE PHYSIOLOGY

Supervisors: Dr. M. S. Luxton and Dr. R. Gibson

"The feeding biology and digestive physiology of *Arion hortensis*."

## 5. Natural Environment Research Council Assistantship

PALAEO LIMNOLOGY-FRESHWATER  
PALAEOECOLOGY

Supervisor: Dr. G. H. Evans

"The Late-Quaternary history of the diatom flora of two nutrient rich meres, Rostherne Mere (Cheshire) and Ellesmere (Shropshire), with particular reference to the history of eutrophication of these meres."

## 6. Local Authority Assistantship

## PLANT ECOLOGY

Supervisor: Dr. T. C. Marks

"The growth and reproduction of *Spartina townsendii* in the Ribble Estuary."

Letters of application, together with a full curriculum vitae and the names and addresses of three referees, should be sent to the appropriate named supervisor(s), from whom further details may be obtained, within three weeks of the appearance of this advertisement. The address for correspondence is:

Department of Biology,  
Liverpool Polytechnic,  
Byrom Street,  
Liverpool L3 3AF.

Informal telephone enquiries will be welcomed: Tel STD (051) 207 3581. Please Quote Reference LP/293. 936(F)

## STUDENTSHIPS—continued

**UNIVERSITY OF OXFORD**  
**M.R.C. STUDENTSHIP**
**NUFFIELD DEPARTMENT OF ANAESTHETICS**  
**RADCLIFFE INFIRMARY, OXFORD**

Applications are invited for a M.R.C./D.Phil. studentship in an active clinical research department, from September/October 1979. The studentship will be in applied respiratory physiology. It will deal with practical and theoretical problems of lung volume measurement and in-vivo blood-gas analysis in the animal laboratory, the Intensive Therapy Unit and the Operating Theatres.

Applicants should have, or expect to gain, a good honours degree in Physiology. Applications, enquiries and further details can be obtained from:

Dr C. E. W. Hahn or Dr A. M. S. Black,  
Nuffield Department of Anaesthetics,  
Radcliffe Infirmary,  
Oxford OX2 6HE.

Telephone: Oxford (0865) 49891  
Ext. 892 (Dr Hahn)  
Ext. 6069 (Dr Black).

973(F)

**UNIVERSITY OF READING**  
**DEPARTMENT OF FOOD SCIENCE**
**S.R.C. C.A.S.E. STUDENTSHIP**

(In association with Unilever Research Laboratory, Sharbrook)

Applications are invited from persons possessing, or expecting to obtain, an Honours Degree (I or II(i)) in a relevant science (e.g. Microbiology, Biochemistry, Chemistry, Food Science) and who wish to proceed to a higher degree by research.

The project is concerned with the mechanisms of the survival of *Salmonella* in foods.

Applications stating age and qualifications and naming two referees should be sent no later than June 8, 1979 to Dr W. F. Harrigan, Department of Food Science, University of Reading, London Road, RG1 5AQ. 886(F)

**UNIVERSITY OF READING**  
**DEPARTMENT OF ZOOLOGY**
**S.R.C. AND N.E.R.C. RESEARCH STUDENTSHIPS**

S.R.C. and N.E.R.C. supported Studentships are available in the following projects:

1. Effects of water on mechanics of soft tissues.
2. Epidemiology of parasites in wild mammals.
3. The physiology of abnormal development *in utero*.
4. Behaviour sequence analysis using observation and physiological monitoring.
5. Trace element metabolism of crayfish.

Applicants should write in the first instance to Professor K. Simkiss, Department of Zoology, University of Reading, Whiteknights, Reading RG6 2AJ giving a curriculum vitae and the names and addresses of two referees. Closing date will be June 6, 1979. 884(F)

**UNIVERSITY OF BIRMINGHAM**  
**DEPARTMENT OF BIOCHEMISTRY**  
**S.R.C./C.A.S.E. STUDENTSHIP**

This award (S.R.C. plus £400 per annum) will be tenable for three years. The student may register for a PhD. The research, on 'The Regulation of  $\alpha$ -Amylase in Pregerminating Wheat' will be in collaboration with the Flour Milling and Baking Research Association.

Applicants should have, or should expect to get, a First or Upper Second Class degree, and should contact Dr D. E. Briggs, Department of Biochemistry, University of Birmingham, P.O. Box 363, Birmingham B15 2TT (Tel. 021-472-1301 ext. 2492).

951(F)

**UNIVERSITY OF OXFORD**  
**DEPARTMENT OF ASTROPHYSICS**  
**S.R.C. C.A.S.E. RESEARCH STUDENTSHIP**

Applications are invited from persons holding or expecting to receive a First or Upper Second Class Honours degree in physics or astronomy for a C.A.S.E. Studentship in conjunction with the National Physical Laboratory, Teddington, to work on the accurate determination of atomic transition probabilities, with applications in astrophysics, and on the accurate measurement of high temperatures by radiative techniques.

Applicants with the names and addresses of two referees and a curriculum vitae should be sent to Professor D. E. Blackwell, Department of Astrophysics, South Parks Road, Oxford OX1 3RQ. 841(F)

**CITY OF BIRMINGHAM**  
**POLYTECHNIC**  
**DEPARTMENT OF SCIENCE**  
**(BIOMEDICAL SCIENCE)**  
**M.R.C.**
**RESEARCH STUDENTSHIP**

Applications are invited for an M.R.C. Studentship commencing on October 1, 1979. The project is concerned with the investigation of malaria *Plasmodium berghei* to infected mouse blood for the presence of potential haemolytic factors. The work will involve a wide range of analytical techniques including isolation of parasites from host cells.

Applicants should have, or expect to obtain, a First or Upper Second Class Honours degree in Biochemistry, Biological Sciences or related subjects, and an interest in Parasitology. The value and conditions of the award will be those of M.R.C. studentships.

Applications giving a full curriculum vitae and names and addresses of two referees should be sent as soon as possible to Dr M. G. N. Angus, Department of Science, City of Birmingham Polytechnic, Franchise Street, Birmingham B42 2SU from whom further details may be obtained (Tel. 021-356-6911 Ext. 253). 865(F)

**UNIVERSITY OF LIVERPOOL**  
**DEPARTMENT OF PHYSIOLOGY**  
**C.A.S.E. STUDENTSHIP**

Applications are invited for an S.R.C. C.A.S.E. Studentship to work on the development and application of immunochemical methods in studies on the chemistry and metabolism of active peptides in brain and gut. The industrial sponsor will be Reckitt and Colman Ltd. Candidates should possess or expect to obtain a good honours degree in Biochemistry or a related subject and should have an interest in peptide synthesis.

Applications, together with the names of two referees, should be received as soon as possible, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/612/N. 949(F)

**UNIVERSITY OF DURHAM**  
**DEPARTMENT OF CHEMISTRY**  
**S.R.C. C.A.S.E. STUDENTSHIP**

Applications are invited for a C.A.S.E. studentship, in collaboration with A.E.R.E. Harwell, for the 'Study of Adsorbed Species Using Inelastic Neutron Scattering Spectroscopy'. The studentship is available from October 1979 for candidates interested in the vibrational spectroscopy and structure of small molecules adsorbed in zeolite frameworks and on metal powders. Experimental work will be carried out in Durham, A.E.R.E. Harwell and at the Institut Laue Langevin in Grenoble, France. It is expected that some of the experimental measurements will be made using the Harwell Linear Accelerator which is nearing completion.

This topic offers the opportunity to gain experience in a wide range of preparative, analytical and spectroscopic techniques, together with experience in using cryogenic, vacuum (medium and UHV) and complex, computer controlled experimental apparatus.

The research will be conducted under the supervision of Professor T. C. Waddington and Dr J. Howard. Standard S.R.C. rates plus £300 per annum for a suitably qualified candidate. Applicants should possess, or expect to obtain, a 1st or upper 2nd class honours degree in chemistry or chemical physics.

Further details can be obtained from Dr J. Howard, Chemistry Department, University of Durham, South Road, Durham DH1 3LE. 931(F)

**UNIVERSITY OF BATH**  
**SCHOOL OF BIOLOGICAL SCIENCES**  
**RESEARCH STUDENTSHIP**  
**IN PLANT PATHOLOGY/**  
**BIOCHEMISTRY**

Applications are invited from students having, or expecting, a good honours degree in biology or biochemistry (preferably including courses in plant pathology and plant physiology).

The project will investigate the role of plant cell walls in resistance to fungal pathogens, especially w.r.t. the interaction between host cell wall and microbial cell wall-degrading enzymes. The study will involve enzyme purification and characterisation, extraction of plant cell walls and lectins, growth of biotrophic fungi *in vitro* and electron microscopy.

The position is available from October 1979 and the applicant will register for a M.Sc./Ph.D.

Applications with curriculum vitae and names of two referees should be sent to Dr R. M. Cooper, Crop Protection Group, School of Biological Sciences, University of Bath, Bath BA2 7AY. 919(F)

**UNIVERSITY OF ABERDEEN**  
**S.R.C. STUDENTSHIP**

Applications are invited for a three-year research studentship awarded to this Department by the Science Research Council. Students interested in the fields of Vertebrate or Invertebrate Physiology or Evolutionary Ecology Geckos should write immediately to the Head of Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen, AB9 2TN. 900(F)

**UNIVERSITY OF NOTTINGHAM**  
**School of Agriculture**  
**SUTTON BONINGTON**  
**LOUGHBOROUGH**  
**S.R.C. C.A.S.E. RESEARCH STUDENTSHIPS**

Applications are invited from persons holding or expecting to obtain a good honours degree in an appropriate field for the following awards.

Department of Agriculture and Horticulture (2 awards)

1. An investigation into the agronomical and physiological factors affecting the production of cereals for seed. Particular emphasis will be placed on optimising the production of numbers of grain suitable for seed. The collaborating body is Rothwell Plant Breeders. (Dr J. S. McLaren)
2. A study of environmental factors affecting cereal growth and development in relation to an accurate computer simulation model of field performance. The project will be primarily concerned with leaf growth, canopy development and water relations. The collaborating body is the Meteorological Office (Bracknell). (Dr J. S. McLaren).

Department of Applied Biochemistry and Nutrition.

The project is concerned with the synthesis and deposition of the proteins in wheat grains. The collaborating company is RHM Research Ltd. (Dr G. C. Blackwood)

Department of Physiology and Environmental Studies.

The project is concerned with physiological studies on seed germination in sugar beet. The collaborating company is a well known Sugar Beet Breeding Company. (Prof. W. J. Whittington and Dr D. Grierson).

Further details about these projects can be obtained from the members of staff mentioned but potential candidates are advised to submit as soon as possible a full curriculum vitae including previous education and current courses, the names and addresses of two referees and where possible a telephone number. 930(F)

## STUDENTSHIPS—continued

QUEEN ELIZABETH  
COLLEGE  
Kensington

(University of London)

N.E.R.C. STUDENTSHIP  
Species diversity in fluctuating  
and constant environments

Applications are invited for the above Studentship, tenable for a period of 3 years, under the direction of Dr M. J. Bazin, Department of Microbiology, Queen Elizabeth College, Campden Hill, London W8 7AH, to whom applicants should send a curriculum vitae together with the names and addresses of two referees.

863(F)

QUEEN ELIZABETH  
COLLEGE  
Kensington

(University of London)

DEPARTMENT OF PHYSIOLOGY

## S.R.C.

## RESEARCH STUDENTSHIP

Applications are invited from good Honours graduates in biological sciences (e.g., Physiology, Biochemistry) for a Ph.D. research studentship funded by the Science Research Council. The successful applicant will join Professor D. L. Yudilevich's research group which is currently investigating *in vivo* the transport of radioactively labelled organic molecules (amino acids, sugars, hormones and drugs) in the perfused placenta and salivary gland. The applicant would be encouraged to extend these studies to the blood-brain-barrier (pial capillaries) and will receive all the necessary assistance from the group.

The Physiology Department at Queen Elizabeth College is active in research and very well-equipped for the proposed project.

The studentship is tenable for three years starting October 1, 1979. Requests for further information and applications, including a full curriculum vitae and the names of two referees, should be made to Professor D. L. Yudilevich, Department of Physiology, Queen Elizabeth College, Campden Hill Road, London W8 7AH.

980(F)

## UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS

## RESEARCH STUDENTSHIP

An S.R.C. Studentship is available in the Condensed Matter (Experimental) Group for the study of Ionic Liquids. The project will involve the application of Neutron Diffraction techniques and use will be made of the neutron beam facilities at A.E.R.E., Harwell and the I.L.L., Grenoble. Data processing will be undertaken on the Cyber 73 at Leicester.

The studentship provides an opportunity to join an active research group that is currently engaged on a number of inter-related projects that are not only of great fundamental importance but are also relevant to the needs of modern technology.

All enquiries concerning this studentship should be made to Dr R. A. Howe, Department of Physics, University of Leicester LE1 7RH.

971(F)

## FELLOWSHIPS

## UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

## A.R.C. POSTDOCTORAL

RESEARCH FELLOWSHIP  
IN CHLOROPLAST  
BIOCHEMISTRY

Applications are invited for a post-doctoral Research Fellowship to investigate the characteristics and control of chloroplast division in wheat leaves under the direction of Professor Rachel Leech. The project will involve the study of the role of the nuclear genome in the regulation of chloroplast division. Preference will be given to applicants with experience in both plant biochemistry and plant ultrastructure.

The appointment, which will be on Grade 1A of the national salary scales for research staff, will be for three years.

Informal enquiries and further particulars from Professor R. M. Leech, Department of Biology. Two copies of applications, giving a curriculum vitae and the names of two referees, should be sent by Friday, June 8, to the Registrar, University of York, Heslington, York, YO1 5DD. Please quote reference number 11/6105.

## EMBO

## European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN  
MOLECULAR BIOLOGY  
AUTUMN 1979 AWARDS

Next deadline: August 31, 1979

EMBO long term fellowships are initially awarded for one year. Applications for a renewal for a second year and subsequently in cases of exceptional scientific merit for a third year are considered.

To be eligible a candidate must hold a doctor's degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are not, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

Successful applicants will be notified of their awards on October 29, 1979.

Further details and application forms may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R. Germany.

W126(E)

CSIRO AUSTRALIA  
Postdoctoral Research Fellow  
Division of Materials Science  
Parkville Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

## Field: CATALYSIS

**General:** The Division is engaged in a broad area of Surface Science, Materials Research and Production Technology. It operates laboratories at Parkville, Fitzroy and Fishermen's Bend in Victoria and at Woodville in South Australia. The appointee will be located at the Catalysis and Surface Science Laboratory, University of Melbourne, Parkville, Victoria.

**Duties:** To participate in a research group studying catalytic processes for fuel synthesis, particularly the use of new zeolite catalysts.

**Qualifications:** A PhD degree in Chemistry or Chemical Engineering or equivalent qualifications.

**Salary:** Research Scientist \$A15,422—\$A18,904 pa or Senior Research Scientist \$A19,572—\$A22,405 pa.

**Tenure:** The Fellowship will be for a period of five years.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 370/346 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 23rd June, 1979.

Applications in U.S.A. and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

916(A)

## An Taisce

## The Heritage Trust

## HERITAGE GARDENS FELLOWSHIP

An Taisce—the National Trust for Ireland intends to appoint a person to catalogue plant collections in Irish gardens of international importance and to undertake related research. The person, based at the National Botanic Gardens, Dublin, will be required to spend most of the time working in gardens throughout Ireland. The fellowship is for an initial one year period renewable annually up to three years. A University degree or diploma in botany or horticulture with experience in horticultural taxonomy and plant identification.

**Salary:** £3,500 to £5,000; assistance will be given with transport and accommodation in the field.

**Due to the present postal difficulties in the Irish Republic, intending applicants should telephone An Taisce (Dublin 681944) for further information and application details.**

W133(E)

## UNIVERSITY OF

SOUTHAMPTON

## Insect Chemistry

Two postdoctoral research fellowships are available for October 1, 1979, to work in a large group concerned with the Chemistry of Insects. Both of the positions will be concerned with Organic synthesis of biologically active compounds but other studies will also be associated with the isolation of compounds involved in insect communication. The post will involve some collaboration with Biologists but no previous experience of biology is required.

## Organic Chemistry

A fellowship is also available on a project concerned with the use of organometallic complexes in organic synthesis.

Salary within the range £4,333 to £4,910.

Applications, including brief curriculum vitae and the names of at least two referees, should be sent, as soon as possible, to Professor R. Baker, Chemistry Department, Southampton University, Southampton SO9 5NH. Ref. No. N. 878(E)

## UNIVERSITY OF

BIRMINGHAM

DEPARTMENT OF

MICROBIOLOGY

## POSTDOCTORAL

## RESEARCH FELLOWSHIP

Biochemist or chemical microbiologist needed to purify cell-wall components responsible for the resistance of gonococci to killing by human phagocytes. The project, which relates to a gonococcal vaccine, is supported by the Medical Research Council for three years from October 1, 1979.

Salary will be in the Research Fellowship 1A range £4,333 to £7,521, plus superannuation. Maximum starting salary will be £5,199.

For further details apply to Professor H. Smith, Department of Microbiology.

Applications (3 copies) including full curriculum vitae and naming three referees should be sent to the Assistant Registrar, Science and Engineering, P.O. Box 363, University of Birmingham B15 2TT, by Friday June 15, 1979.

Please quote reference NM5. 868(E)

## FELLOWSHIPS—continued

**UNIVERSITY OF  
SOUTHAMPTON  
SCHOOL OF BIOCHEMICAL  
AND PHYSIOLOGICAL SCIENCES**  
Applications are invited for a  
**POSTDOCTORAL  
RESEARCH FELLOWSHIP**

in the Nutritional Group of the School of Biochemical and Physiological Sciences to work in collaboration with Dr D. A. York on an investigation of membrane composition and function of obese mice.

Three years postgraduate experience in Biochemistry (preferably in some aspect of lipid or membrane research) is essential for this appointment, which will be for two years, commencing by September 1, 1979 or as soon as possible thereafter. Starting salary £4,776 per annum. USS benefits.

Applications in the form of curriculum vitae and the names of two referees should be sent as soon as possible to Mrs P. Vaughan-Smith, The University, Southampton, SO9 5NH, quoting reference 1072/R/N 874(E)

**UNIVERSITY OF WARWICK  
RESEARCH FELLOWSHIP  
IN CONTROL THEORY**

Applications are invited for the above post tenable for two years in the area of nonlinear control theory in the Control Theory Centre of the Department of Engineering. Applicants should have a Ph.D. in Control/Systems Theory or Mathematics with an interest in Control Theory. Salary on the Research Range 1A scale: £3,883 to £6,555 p.a. (under review). Application forms and further particulars from the Academic Registrar, University of Warwick to whom applications should be sent as soon as possible. Please quote Ref. No: 39/4A/79. 866(E)

**UNIVERSITY OF  
SOUTHAMPTON  
SCHOOL OF  
BIOCHEMICAL  
AND  
PHYSIOLOGICAL SCIENCES  
BIOCHEMISTRY DEPARTMENT  
POSTDOCTORAL  
RESEARCH FELLOW  
BIOORGANIC CHEMISTRY**

Applications are invited for a POSTDOCTORAL FELLOWSHIP in the field of Bioorganic Chemistry. The successful candidate will participate in studies in the Biosynthesis of Natural Compounds. Applicants should have at least three years postgraduate experience in synthetic organic chemistry and should also be conversant with some basic biochemical techniques. A knowledge of HPLC and the use of radioisotopes is also desirable. The work will entail the synthesis of labelled precursors and their incorporation into natural products in biological systems. The appointment is for one year in the first instance commencing immediately, with the possibility of an extension for a second year.

Starting salary £4,776 per annum. U.S.S. benefits.

Applications with date of birth, curriculum vitae and the names of three referees should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, by June 15, 1979. Please quote reference 1074/R/N. 881(E)

**POSTDOCTORAL FELLOWSHIP:** candidates with experience in molecular biology, protein- or nucleic acid chemistry. Applications to: Dr Gernot Walter, Institut für Immunbiologie der Universität Freiburg, Stefan-Meier-Str. 8, D-7800 Freiburg, W-Germany. W132(E)

**UNIVERSITY OF WARWICK  
POSTDOCTORAL  
RESEARCH FELLOWSHIP  
in  
BIOLOGICAL SCIENCES**

Applications are invited for a position as Research Fellow in a small group studying the ecology of aquatic viruses. The project will involve studies of (a) environmental effects on bacteriophage multiplication, (b) phage infection of microbes attached to surfaces, (c) genetic interactions (phage-host and phage-phage) in aquatic habits. Ideally, applicants should have a Ph.D. in Microbiology. Previous experience with bacteriophages and/or an interest in mathematical modelling would be an advantage. The appointment is funded by the Natural Environmental Research Council for three years commencing in October 1979. The starting salary will be £3,883 on the Research Range 1A scale, £3,883 to £6,555 per annum (under review). Applications (two copies) either typewritten or in black ink, giving details of age, qualifications and experience and the names of two referees should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No: 41/A/79, as soon as possible. Informal enquiries to Dr S. B. Primrose, Department of Biological Sciences, by letter or telephone 0203 24011, ext. 6019. 869(E)

## GRANTS

**UNIVERSITY OF  
LEICESTER  
RESEARCH**

**leading to Higher Degrees in the  
DEPARTMENT OF CHEMISTRY**

Grants are available for research studies leading to the degree of Ph.D. Research is active in all branches of Chemistry, examples being: Organophosphorus Chemistry, Inorganic Fluorine Chemistry, all forms of Spectroscopy including E.s.r. Spectroscopy, Radiation Chemistry, and the Study of Solvation.

Applications are invited from persons holding, or hoping to be awarded during 1979, a degree with First or Second Class Honours (Upper Division) in Chemistry, or equivalent qualifications.

For further information and application forms please write to Professor M. C. R. Symons, Department of Chemistry, University of Leicester LE1 7RH. 896(H)

## ASSISTANTSHIPS

**UNIVERSITY OF GLASGOW  
DEPARTMENT OF  
MICROBIOLOGY  
RESEARCH ASSISTANT**

A postgraduate research assistantship, funded by the S.R.C., is available for work on the mechanism of action of the thymidine analogue bromodeoxyuridine during bacterial growth and differentiation. Applicants should possess, or expect to obtain, a degree in microbiology or related discipline and have an interest in microbial physiology and genetics.

The appointment is for two years, from September 1, 1979, with an initial salary of £3,689 per annum (under review) on scale 1B for research and analogous staff.

Applications, including a brief curriculum vitae and the names and addresses of two referees, should be sent to Dr J. E. Coote, Microbiology Department, University of Glasgow, Garscube Estate, Bearsden, Glasgow G61 1QH, as soon as possible.

In reply please quote Ref. No. 4457M. 870(P)

**UNIVERSITY OF GLASGOW  
RESEARCH  
ASSISTANTSHIP/  
LECTURESHIP IN PHYSICS**

The University of Glasgow wishes to expand its research on gravitational wave detection and offers a special appointment in the Department of Natural Philosophy for work in this field. For the first three years from October 1, 1979, the post will be supported by a research grant made by the S.R.C. to the University in support of the work of Professor R. W. P. Drever and his group and at the end of this period it will be taken over by the University as a tenured lectureship. The research programme includes development and use of gravitational wave detectors using laser interferometry and other techniques. Correlated observations made with gravitational wave detectors at Glasgow and at California Institute of Technology are envisaged. A suitable applicant might be an experimental physicist or electrical engineer with at least three years postdoctoral experience. Previous work on highly sensitive or high precision experiments in any field could be an advantage.

Initial appointment will be at Research Assistantship level within Range 1A of the Research and Analogous Staff Scales (£4,910 to £6,355), with placement according to qualifications and experience. Appropriate superannuation scheme will apply.

Further particulars may be obtained from the Secretary of the University Court (Room 18), University of Glasgow, Glasgow G12 8QQ, to whom applications (8 copies), giving the names and addresses of three referees, should be lodged on or before June 22, 1979.

In reply please quote Ref. No. 4459M. 942(P)

**UMIST  
RESEARCH ASSISTANT**

A Research Assistantship is available in the Department of Chemistry to work with Dr. C. A. McAuliffe on a project aimed at developing a facile reversible molecular hydrogen storage system based on simple transition metal complexes. This postdoctoral position would suit a synthetic transition metal chemist or a physical chemist interested in adsorption of gases on solid surfaces. An interest in spectroscopic techniques applicable to surface phenomena and in e.p.r. would be an advantage. The appointment will be initially for one year.

Salary is on the range £3,883 to £4,382 per annum (under review).

Application by letter, quoting reference CH/73/A1 including a curriculum vitae plus the names of two referees should be addressed to Dr. C. A. McAuliffe, Department of Chemistry, UMIST, P.O. Box 88, Manchester, M60 1QD (Phone 061-236 3311 Ext. 2098). 895(P)

**UNIVERSITY COLLEGE  
LONDON  
DEPARTMENT OF GEOLOGY  
ASSOCIATE  
RESEARCH ASSISTANTSHIP  
POSTDOCTORAL**

This post, funded by the N.E.R.C. over a 3-year period, is for an experimentalist to study the influence of cavities and cracks on mechanical properties of rocks under conditions simulating those in the Earth's crust and mantle. The research will utilise high pressure/high temperature apparatus already available at U.C.L. but the A.R.A. will be expected to develop techniques for measuring acoustic velocity in samples undergoing deformation. An interest in the theoretical interpretation of materials deformation and/or the study of microstructures by electron and optical microscopy will be welcome. The research is supported by good laboratory and workshop facilities, technical staff, and grant for equipment, and has important applications in crustal deformation and fracture, the movement of fluids in the crust, and in the interpretation of geophysical observations related to crustal structure and geodynamics.

Salary range £4,261 to £4,805 plus £502 London Allowance; U.S.S.

For further details write to Dr S. A. F. Murrell, Department of Geology, University College London, Gower St., London WC1E 6BT, to whom applications, including curriculum vitae and the names of two referees should be sent by July 20, 1979. 905(P)

**IMPERIAL COLLEGE OF  
SCIENCE AND  
TECHNOLOGY  
DEPARTMENT OF BIOCHEMISTRY  
POSTDOCTORAL  
RESEARCH ASSISTANTSHIP**

A postdoctoral Research Assistant is required for Freeze-Etch Investigations of Synapse and Cell Membrane Ultrastructure in Muscles affected by Muscular Dystrophy. Previous experience in Membrane Research and Electron Microscopy is desirable. The successful applicant will join an active, well-equipped research group, preferably starting on October 1, 1979.

The position, supported by the Wellcome Trust, is for an initial period of one year, with the possibility of extension for a second year. The starting salary (according to age and experience) will be between £4,762 and £5,835, including London Allowance and U.S.S. benefits.

Applications, including a curriculum vitae, the names of two referees and a full statement of research interests and experience, should be sent to Dr David Shotton before June 20, to the Department of Biochemistry, Imperial College, London SW7 2AZ, England, or subsequently to the Marine Biological Laboratory, Woods Hole, Mass. 02543, U.S.A. 926(P)

## SYMPOSIUM

**CATALYSIS AND CONTROL OF  
POLYMERISATION**

The 8th Biennial Manchester Polymer Symposium will be held at UMIST on Tuesday and Wednesday, April 1 and 2, 1980.

Aspects of the control of the structure of commodity polymers by the choice of Ziegler-Natta catalysts will be discussed on the first day. Invited Lecturers will include Dr D. Ballard (ICI Corporate Laboratory), Dr P. J. T. Tait (UMIST) and Professor P. Teyssie (Liège). Catalysts for speciality polymers will provide the topic for the second day when Invited Lecturers will include Professor G. Wegner (Freiburg) and Professor C. H. Bamford (Liverpool).

The programme will also provide time for a limited number of Contributed Papers. Offers of contributions should be sent to Dr A. S. Dunn at the UMIST Chemistry Department before July 16, 1979.

The symposium programme will be available in December 1979: requests for copies should be addressed to Barbara Halloran, UMIST, P.O. Box 88, Manchester M60 1QD. Tel. (061) 236 3311, Ext. 2753. 894(M)

## Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases—such as *Eco* RI—specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical

credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings... and beginnings.

Please supply more information about:

☐ Restriction nucleases ☐ DNA ligase ☐ Terminal transferase

☐ Please send a current Miles Biochemical Catalog.

### : Solving the Mystery

**Professor John Imbrie and  
Katherine Palmer Imbrie**

*May 1979 £6.95 224pp 0 333 26767 2 illustrated*

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' — why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

Circle No. 04 on Reader Enquiry Card.

### Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible;  $\exp(a)$  is preferred to  $e^a$  if 'a' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

Accumulation of an mRNA and protein in interferon-treated Ehrlich ascites tumour cells	P. J. Farrell, R. J. Broeze and P. Lengyel	523
Hydroxylamine stimulates carboxylase activity and inhibits oxygenase activity of cyanobacterial RuBP carboxylase/oxygenase	K.-I. Okabe, G. A. Codd and W. D. P. Stewart	525
Nitrogen fixation in coral reef sponges with symbiotic cyanobacteria	C. R. Wilkinson and P. Fay	527
Antiviral antibody reacting on the plasma membrane alters measles virus expression inside the cell	R. S. Fujinami and M. B. A. Oldstone	529
<i>In utero</i> sister chromatid exchange analysis for detection of transplacental mutagens	D. Kram, G. D. Bynum, G. C. Senula and E. L. Schneider	531
The pair of central tubules rotates during ciliary beat in <i>Paramecium</i>	C. K. Omoto and C. Kung	532
Increased incidence of abnormal nasal cilia in patients with retinitis pigmentosa	G. B. Arden and B. Fox	534
Membrane fluidity of a fatty acid auxotroph grown with palmitic acid	H. Hauser, G. P. Hazlewood and R. M. C. Dawson	536
Cholesterol modulates activity of calcium-dependent ATPase of the sarcoplasmic reticulum	T. D. Madden, D. Chapman and P. J. Quinn	538
ATP induces nucleotide permeability in rat mast cells	S. Cockcroft and B. D. Gomperts	541

## Volumetrics Pipettors

50  $\mu$ l, 100  $\mu$ l

Accuracy and reproducibility better than  $\pm 1\%$ . Priced as low as \$2.00 ea.

VOLUMETRICS WORK STATION holds 2 Pipettors and 250 tips (shown without dust cover).

## Pasteur + Plus

DISPOSABLE PLASTIC TRANSFER PIPETTES

Regular  
Ultra lean-tubed

A safer alternative to the glass pipette. No bulb to leak, safe one time use without risk of contamination.

For volumes up to 3 ml. 21 to 24 drops/ml delivery.

## Tips

We carry a full line of disposable polypropylene tips for our own and many other pipettors.

## Ultipettes

Excellent for Pasteur pipetting. Five adjustable models: to 1 ml, to 2 ml, to 5 ml, (with air bleed for optional use); 2 ml and 5 ml models also available in PTFE for acids and solvents.

## Finnpipettes

OVER 70,000 IN USE WORLD WIDE.

Accurate, reproducible adjustable micropipetting. 5 instruments to cover the range from 1  $\mu$ l to 5,000  $\mu$ l.

## This Publication . . .

## THIS IS AN ESSENTIAL RESEARCH TOOL . . .

Life sciences demand the best research tools.

**Biological Abstracts RRM (Reports, Reviews and Meetings)** will be BIOSIS' 1980 companion to **Biological Abstracts**, covering 125,000 Proceedings, Meetings, Symposia, Bibliographies, Review Journals, Monographs and much more. **BA RRM** will provide the following features in addition to a full bibliographic citation:

- Arrangement of items by **BA** subject classification
- A "Content Summary" that displays the subject content of these items, including taxonomic names
- Author's address
- Language of the original document

For more information on this invaluable reference tool, contact our User Services Department.

## Recombinant DNA: now is the time for Congress to act

EVER since scientists first suggested that the uncertainties of recombinant DNA research made it advisable to agree on guidelines for containment levels, there has been no logical reason why research in private industry should be carried out under different conditions from university laboratories. After all, the essential concern has been over the potential health risks associated with this research, and such dangers do not differ from one context to another. Nor should one assume that industrial scientists are any more scrupulous than their academic colleagues.

There has thus always been a strong case for extending the guidelines established by the National Institutes of Health for federally-funded research workers in the US to cover the private sector as well (a member of the NIH's Recombinant DNA Advisory Committee recently called it "one of the most bizarre situations in the history of US science and technology" that this was not already the case). The essential question has not been whether this should be done, but how. And it has been the suggested answers to the 'how' questions, embroidering in various ways what might otherwise appear to be a relatively simple legislative concept, that have brought doom to a succession of congressional initiatives.

In the meantime, the process of developing, administering and revising the NIH guidelines has been proceeding relatively smoothly. Many scientists continue to believe that, even in their current form, the guidelines are too restrictive, and to baulk at the extra paper work involved. Others admit, however, that while some risk experiments have tended to confirm certain types of risks as being relatively small, others have indicated hitherto unanticipated potential hazards (such as the ability of DNA strands to induce tumours in laboratory animals). And that as long as these uncertainties remain, which itself is unpredictable, then some type of regulatory framework is necessary to cope with them.

For non-federally funded research, however, the picture remains confused. In the absence of new legislation, attempts have been made to fit the control of research using recombinant DNA techniques into existing legislative and institutional responsibilities. But the novelty of the hazards means that the fit has been an uncomfortable, and possibly untenable one. Thus Mr Califano, Secretary for Health, Education and Welfare, has said that he is reluctant to use powers granted to him under the Public Health Service Act, as some have been suggesting, as he is not sure whether the act is appropriate to the DNA case. In turn the Food and Drug Administration has decided that it probably lacks the legal power to require that all research leading to products submitted for licensing be carried out under the NIH guidelines as it had earlier been proposing to do.

The director of NIH has agreed that companies which express a willingness to comply voluntarily with the existing guidelines would be able to register with the NIH to have their research procedures approved. But the NIH is not, and has no desire to be, a regulatory agency.

(The Environmental Protection Agency and the Department of Labour's Occupational Safety and Health Administration have both kept relatively quiet on the issue, but in both cases there seems to be uncertainty over how to proceed with what remains a conjectural hazard.)

In the circumstances, there now seems a good chance that a new legislative initiative in the US Congress would be welcomed by many sides in the debate. To members of the Administration and federal institutions it would provide a clear delineation of roles and responsibilities in what will otherwise remain a murky situation. To private industry, although opposed in principle to government regulation, it should provide considerably more credibility than current promises to comply voluntarily with the NIH guidelines. And to environmentalists, public interest groups and labour unions, it would signal that private industry was not being given privileged status in the DNA debate (while also providing a channel, if minimal, for public participation in the type of debates that are constantly being urged on the future direction of new technologies with important social implications).

As with the previous legislative attempts, of course, the most controversial issues will inevitably be on the procedural, rather than the technical, aspects of complying with the guidelines. The fact that industry has already indicated that it is willing to comply voluntarily with the guidelines—and the extent to which industry spokesmen have gone to confirm that even at present, private research workers are following recommended physical and biological containment levels—shows that the inclusion of this aspect in new legislation should not provide too much of a problem. The sticky issues, however, will be over the appropriate forms of accountability and responsibility—over who should have access to the decision-making process, on what basis, and what should be done about data needed for the purposes of regulation but which a firm considers to contain information that would be valuable to a commercial competitor.

These are all political questions. At present they are being resolved by default by conventional means, with the decision-making agenda drawn up and controlled by those who stand to gain financially from a successful outcome to the research. It is up to those who, we hope, are now considering possible forms for legislation to decide whether this is the way they wish it to be, or whether to take bolder steps (such as involving trade union representatives in the decision-making process at a local level). It will take a political desire for change to carry it through, but a desire with which Mr Califano has already indicated his sympathy by expanding public interest representation of the RAC last December. RAC has, like Britain's Genetic Manipulation Advisory Group, been held up as a model pointing to the future direction of public participation in technological decision-making. Despite current limitations, we feel that this direction is the right one. And that regulation extending the NIH guidelines to industry should reflect this conviction. □

# Computers lose on the swings and the roundabouts

Tight university research budgets are contributing to a shortage of computer science graduates in the US. But concern is also growing about the social effects of automation.

**David Dickson reports**

NEXT Saturday, half a million members of the Communication Workers of America are holding a national "Job Pressures Day" to protest at the way in which automation is dehumanising working conditions. No one will stop work, the intention is to draw public attention to the issue through informational picketing and other activities under the general slogan "we are people not machines".

The action is claimed to be unprecedented for a major US union, most of which keep strictly to the conventional issues of wages and working hours. But it heralds a trend within the US labour movement which, fuelled by evidence that automation may finally be resulting in the unemployment previously predicted but unrealised, promises to grow substantially over the next few years.

Even without these new complaints about working conditions, the manpower implications of computers—a subject of hot debate in the late 1950s and 1960s, but one that subsided as economic prosperity cushioned any significant impact—are once again causing serious concern in policy-making circles.

On the one hand, support is declining for experimental computer science in US universities, and attracting good staff and students has become a problem. As a result, there are not enough qualified graduates for industry's needs. Many computer companies now face major difficulties in recruiting staff and have expressed their concern to the Office of Science and Technology Policy.

A report published last month by an advisory committee to the National Science Foundation says that as a result of funding difficulties, computer science research is now in a "critical" situation. University programmes are declining, just when the size and quality of research and training should be increasing to meet industry's needs. The report points out that, with obsolete equipment and inadequate finance, many of the best staff are now being recruited away from universities, whose research laboratories were originally responsible for such central innovations as time-sharing techniques, virtual memory systems and file protection mechanisms.

A particular concern, the committee says, is the fall in the number of computer science doctorates in the past

two years. "Because of its leverage in stimulating research, retaining faculty and capturing the interest of superior students, the most important requirement is the establishment and maintenance of outstanding university research facilities," it says. This could be achieved by injecting as little as \$15 million a year, based on five capital grants of \$2 million to separate institutions, plus running costs for each for the following five years. OSTP is now trying, with the support of industry, to persuade the Office of Management and Budget that this will be money well spent.

But while the management side of industry is complaining about a shortage of qualified recruits, labour is concerned about those who will lose their jobs as a result of automation. Until recently, the conventional wisdom was that unemployment was outweighed by the extra jobs created through increased prosperity. Now, with a stagnant economy plus the rapid incursion of automation into previously untouched areas such as office work, there are doubts about this equation.

A typical survey carried out by the Society of Manufacturing Engineers predicted recently that 20% of the labour directly involved in the final assembly of automobiles will be replaced by machines—such as robot

welders—by 1985, and 50% by 1995.

Similarly, a Bureau of Labour Statistics report on telecommunications technology concludes that "the anticipated strong demand for communications will probably modify the adverse effects on employment, but can no longer offset them. As a result, employment is expected to decrease slowly into the mid-1980s, significantly altering job skills and occupational composition."

Such automation seems likely to result in a "substantial permanent sector of unemployment", as a result of society's inability to cope with the effects of new technology, predicts Robert T. Lund, a senior research associate at MIT's Centre for Policy Alternatives. Part of the problem, he suggests, is that the 1950s automation scare which failed to materialise has led to a false sense of security.

Some indication of the size of the problem may be given when the Office of Technology Assessment produces the results of a survey it is conducting as part of a broader project on the social impact of data processing systems, with a view to seeing whether any Congressional action may be needed. "It is certainly an issue that deserves more attention than it has been getting," says Mr Stephen Doyle, group manager for telecommunications at OTA.

Meanwhile there is discontent among those who are at the receiving end of the new technology. A survey conducted by the University of Michigan has just reported that, for the first time, there was a decline in the national level of job satisfaction, as measured between 1973 and 1977. The survey of 1,515 workers found that 36% felt their skills were underused, and 32% that they were "overeducated". There was a "slight but significant" drop in overall job satisfaction.

The unions are already beginning to react, largely in response to rank-and-file pressure. In addition to next week's WA demonstration, members of the United Auto Workers made strong demands at a recent conference for tougher terms on retraining, monitoring technical change and giving early notice of automation plans.

Mr Glenn E. Watts, CWA president, goes further. In a recent article he said that his union believes major technological advances should be held in check until a human impact study has been made, just as environmental impact studies are carried out in other circumstances. "If some workers today are bored and alienated, the degrading of work itself must be recognised as part of the problem." □

## FDA backs off attempt to control private DNA research

THE US Food and Drug Administration has concluded that it probably lacks the legal authority to regulate recombinant DNA research in private industry, as it had previously announced its intention to do following a directive from Health Secretary Joseph A Califano last December.

Instead, the FDA plans to encourage companies to comply voluntarily with the guidelines that have been established by the National Institutes of Health for federally-funded research. The NIH is itself recommending some amendments to the guidelines to make them more acceptable to industry.

Two weeks ago, however, the NIH's Recombinant DNA Advisory Committee passed a resolution recommending that private industry be legally required to observe the guidelines. It is now up to Mr Califano to decide whether a scheme of voluntary compliance is adequate, or whether to seek another route for regulation—possibly involving a new legislative initiative.

Following the failure of numerous attempts in the past to extend the NIH guidelines to industry, Dr Fredrickson, director of NIH, announced last year that companies would be able to register with the NIH—if they wished—to have containment levels for proposed experiments approved.

So far, however, companies have been reluctant to register, fearing that compliance with some sections of the guidelines would require them to divulge commercially-sensitive information. At least one company—Genentech, in San Francisco—is now conducting experiments with 60 litres of culture which would have required submitting full details to the RAC for a special exemption from prohibition under current NIH procedures.

The NIH is now proposing to add a new section to the guidelines to meet

such fears. For example, although academic scientists wishing to have a new host-vector system approved by the director of NIH make available full details of the system and its proposed use, this would be waived for private companies, who say it could require disclosing commercial secrets.

Under the proposed addition to the guidelines, private companies would set up their own institutional biohazard committees. But members of such committees would be exempt from the requirement that they should not be involved in approving a project in which they had a financial interest.

The NIH has also gone to some lengths to establish that it would be a criminal act for any member of the RAC, as "temporary government employees", to divulge confidential commercial information submitted to the committee, and that this information would therefore be immune to the Freedom of Information Act.

At a meeting with HEW general counsel Mr Peter Libassi last week, industry representatives said they were reasonably happy with the new proposals as a basis for voluntary compliance. Public interest and labour representatives, however, were adamant that a voluntary system would not work and that some form of legal back-up was necessary. They also urged that the Environmental Protection Agency and the Occupational Safety and Health Administration take a more active role.

The position on legal controls has been complicated by the FDA's decision. Last December, coinciding with the publication of a revised version of the guidelines and following a directive from Mr Califano, the FDA published a "notice of intent" to introduce regulations. These would require a firm submitting a product

*Califano: he must decide*

for licensing by the FDA to demonstrate that any recombinant DNA research carried out in connection with the product had been done in accordance with the NIH guidelines.

Pharmaceutical companies, however, challenged whether the FDA had the authority to do this under the terms of the federal Food Drug and Cosmetic Act, claiming that the agency's authority was restricted to clinical trials and marketing.

Dr C. W. Pettinga, executive vice-president of Eli Lilly and Company, commented: "In our view the proposal must be carefully evaluated because it could evolve into the regulation of basic research, an undesirable circumstance from a public policy standpoint and clearly not warranted in view of the experience with recombinant DNA technology."

No public reply has yet been made by the FDA. But in the light of these and similar comments, officials in the agency confirmed last week that the proposal to introduce new regulations had been dropped and that support was being recommended for the voluntary compliance scheme as being proposed by the NIH.

Dr Fredrickson is now expected to forward these comments, as well as both the NIH's proposals and the RAC resolution, to Mr Califano—who will have to decide how to take things from there.

**David Dickson**

## Plan for early warning on social effects of biomedical advances

THE National Commission for the Protection of Human Subjects, a body set up in 1974 to study the ethical, social and legal implications of advances in biomedical and behavioural research and technology, has recommended setting up an advisory commission "to anticipate the probable effects of research and technological advances for individuals and society, and to stimulate public participation in decision-making".

This recommendation has arisen from a special study conducted by the commission, whose conclusions were published in the *Federal Register* last

week. The commission says that the results of the study showed both a perceived need for a programme to assess the social impact of technology, and a need to facilitate public information and public participation in research and technological innovations and the policy decisions that result.

"These findings suggest that a mechanism should be established to monitor and evaluate innovations and to provide an early warning system in which the probable effect of innovations in biomedical and behavioural research and technology can be assessed publicly, prior to develop-

ment of widespread dissemination", the commission says. Existing entities, such as those attached to the National Academy of Sciences or the National Institutes of Health, served narrower constituencies and goals, and the independence and broader mandate of a new body were needed, it says.

"The commission should not be dominated by health professionals, for its main purpose would be to facilitate widespread debate involving all segments of society in the ethical and policy issues that affect all people and about which diverse views should be heard." □

# California report pinpoints hazards in layout of Three Mile Island control room

In early May, California's governor Edmund G. Brown Jr called for a national moratorium on construction of nuclear power plants and declared himself to be "at the forefront of the antinuclear movement". Some political observers have suggested that his actions represent a new expression of his presidential ambitions, but the governor also seems to be taking seriously a report prepared by his staff that condemns the state of 'human factors engineering' in the nuclear industry. In a letter to Nuclear Regulatory Commission (NRC) chairman Joseph M. Hendrie, Brown wrote: "I am informed that the design of nuclear power plant control rooms may represent a significant safety hazard".

A copy of this staff report, together with some of the supporting documentation, has become available to *Nature*. The report was prepared by Wilson Clark, Assistant to the Governor for Issues and Planning, and three assistants, two of whom have experience in nuclear engineering. It concludes that many nuclear power plants "are poorly instrumented and designed for adequate reactor operator control . . . Modern nuclear technology is harnessed by antiquated control technology which represents a clear and present hazard."

Clark summarised the report's conclusions in a letter to the chairman of the Presidential Commission on the Accident at Three Mile Island, John G. Kemeny. He cited the NRC's preliminary evaluation of the Three Mile Island accident as a vindication of his belief that poor design for human operation were "a leading, if not the leading factor, in the near-disaster at Three Mile Island." He catalogued three main hazards covered in his report that bear on Three Mile Island:

- poor layout, making plant operation difficult and dangerous;
- inadequate display of control room information; and
- confusing and incomplete operational procedures which lengthen operator responses, decreasing reliability.

Clark's point has been made before, but the issue generated little interest until the series of interrelated human and instrumentation errors at Three Mile Island. The famous Reactor Safety Study, WASH-1400, which gave the nuclear industry a generally clean bill of health, criticised the design of controls and displays and their arrangement on operator panels. Later, a task force of the Electric Power Research Institute (EPRI) expressed similar criticism and recommended that EPRI review the problem. The review was

conducted by the Lockheed Missiles and Space Company and published in late 1976. Although the conclusions of the Lockheed/EPRI report were generally low key, the illustrations were devastating. With such understatement as "the study findings paint a rather negative picture" the report catalogues a substantial list of design faults that could directly affect an operator's ability to react quickly in an emergency. These include:

- massive arrays of identical control/display units with no clearly identified subpanel grouping;
- control levers so large that individual control panels expand to enormous size;
- separation of related panels into two areas so that two operators are required to coordinate their actions even when separated by as much as 50 feet; and
- placement of gauges so high that an operator cannot read them without standing on a footstool, or on a wall opposite the location of related control levers.

Even such a simple matter as the number, placement and ease of replacing signal lamps can have serious consequences. The Lockheed/EPRI study found that "indicator reliability is a problem and there are a surprising number of burned-out, single lamp indicators at any given time" in the reactors surveyed. Warning lights are so numerous that many operators become cavalier about 'nuisance alarms'. And to replace burned-out lamps operators sometimes stand precariously on a control panel.

The Clark report shows how prophetic this passage of the 1976 study was to be. In March 1978, an operator dropped a light bulb into an open con-

trol panel at California's Rancho Seco plant, while trying to fix a burned out indicator. The resulting short circuit caused the reactor to shut down, knocked out two-thirds of its temperature, pressure, flow and level signals, and cut off auxiliary feedwater for seven minutes. Clark concludes: "Had other safety systems not performed adequately, this transient could have been similar to the accident at Three Mile Island, which experienced a loss of auxiliary feedwater cooling for only eight minutes."

Governor Brown's team also cited a study of the Zion nuclear power plant by Alan Swain in 1975, for the NRC. According to the Clark report, the owner of the Zion plant had been able to suppress distribution of the document, which had found in a 'talk-through' of procedures to use in a serious accident, that "even experienced operators had some difficulty in locating particular controls and displays."

It remains to be seen what action will be taken to improve the confusing array of instruments, dials and switches facing reactor operators, but the NRC has at least acknowledged the problem. A recent staff report on reactors designed by Babcock and Wilcox (who designed the plant at Three Mile Island) states: "Human factors engineering has not been sufficiently emphasised in the design and layout of the control rooms. The location of instruments and controls in many power plants often increases the likelihood of operator error or, at the least, impedes the operator in efficiently carrying out the normal, abnormal, and emergency actions required of him."

John Douglas

## US to study health effects of accident

THE US Department of Health, Education and Welfare announced last week that it is to carry out a number of surveys of the possible health effects on those who were exposed to radiation as a result of the nuclear accident two months ago at the Three Mile Island nuclear power plant in Pennsylvania.

One survey will cover pregnant women living within 10 miles of the plant, who will receive regular health checks throughout their pregnancy. Their children will be monitored for the first few months after birth. The National Institute of Mental Health will carry out a survey of a representative group of people "subject to the strain of the accident", and a

further study will examine the health of the workers at the plant.

In addition there will be a general survey of the health of 50,000 residents living within five miles of the plant. "It's just common sense to do this. There is no reason for alarm. I said some time ago that we would study the population, and that we would particular focus on pregnant women", Health Secretary Joseph Califano said last week. The survey will be financed by the Center for Disease Control and the National Cancer Institute. State officials hope to continue the study on a year-to-year basis for up to 20 years.

David Dickson

## Support grows for rival conference on development

SEVERAL hundred non-governmental organisations have already expressed interest in participating in an alternative conference which is being planned to take place in parallel with the United Nations Conference on Science and Technology for Development in Vienna at the end of August.

Unlike the official conference, which will concentrate on political mechanisms for stimulating the contributions of science and technology to development, the alternative conference will consider specific topics for action. High on the preliminary agenda are plenary sessions on nuclear energy in Third World countries, environmental aspects of development, the role of multinational corporations, and the implications of the arms race. These sessions will take place in Vienna's Kongresshaus.

A number of working groups are also planned, to run for the full ten days of the conference (August 19 to 29) with the aim of producing specific proposals for action. In particular, there will be discussions about information and financial mechanisms that might be established to support the work of non-governmental organisations after the conference. "This is one of the most important things that we can do at Vienna", says Dr Karim Ahamed of the Natural Resources Defense Council in New York, chairman of the conference organising committee.

"We want to see the extent to which non-governmental organisations can, for example, stimulate technology assessment activities in Third World countries which could be brought to bear on government efforts. And we also want to find out what private and public sources of funding are available to support these efforts."

The organising committee, which has a planning board made up of 14 international organisations, is already preparing an extensive document commenting on the proposals for action that will be discussed at the official conference, and pointing out areas—such as the need for appropriate technologies, or the role of women in development—which it feels have been neglected in official discussions.

"One particular goal will be to see if we can create mechanisms for monitoring what happens after UNCTSD, and exposing it to public view in an effort to make governments keep up to their promises," Mr Ward Morehouse, another member of the committee, said. □

## Max Planck Society sets up three new research institutes—and cuts off support for others

THE Max Planck Gesellschaft (MPG), which spends DM750 million a year on research in West Germany, has started to renew and restructure several of its 50 institutes. It is following a tradition of, from time to time, taking up new fields in exchange for others that have matured or have not developed according to the MPG's expectations.

Last March, the MPG Senate, for the first time in five years, approved the setting up of new institutes (MPI) and gave the green light for three of them straightaway: an MPI of Quantum Optics (Directors: Professors Karl-Ludwig Kompa, Herbert Walter and Siegbert Witkowski); an MPI of Psycholinguistics (Director: Professor Dr Willem J. M. Levelt); and an MPI of International and Foreign Social Legislation (Director: Professor Dr Hans F. Zacher).

In addition, one or two project groups working closely with clinical establishments (eg in universities) are to be set up to augment medical research within MPG. The content and orientation of their research is not yet decided, but it is likely that cancer research will be among the new fields.

The decisions to set up the three new institutes have been taken after several years of successful work by project groups. (This is an important condition within the MPG for the establishment of a new institute.) The new MPI of Quantum Optics is building on the work of the project group for laser research, which itself was hived off four years ago from the MPI of Plasma Physics (IPP). And the future Institute of Psycholinguistics, which will research the structure and use of natural language is building on work already done at the Netherlands University of Nijmegen. The decision to site the latter at Nijmegen is seen as an example of MPG's emphasis on European cooperation. The MPG, which is financed jointly by the federal research ministry and the *Länder*, hopes to fund its new activities from higher growth rates in the budget (6–8% per annum instead of an average of about 3% during recent years of stagnation).

The MPG has also decided to close down work at two of its institutes. Terminating work in a particular field or closing an entire institute is usually done when similar research is being carried out in universities and other research establishments (and mostly when the head of the institute retires).

Thus Professor Jürgen Aschoff's research at the MPI of Behavioural Physiology runs out with his retirement because biorhythms are being researched simultaneously at other places. (His famous 'bunker' will continue to be available to researchers!) For similar reasons the work on nuclear physics at the MPI of Chemistry in Mainz is to run out and be replaced by the new main field of geochemistry.

On average, over the past 10 years, one institute or department within the MPG has been closed or transferred to another agency each year. In the majority of cases the public has been aware of little of the concomitant tensions or problems. Not so, however, in the case of the institute founded in 1970 by Carl Friedrich von Weizsäcker in Starnberg with the ambitious title of Max Planck Institute of Research into the Living Conditions of the Scientific-Technological World. The founding of the institute created a stir in particular because of the all-embracing formulation of its brief (which prompted *Der Spiegel* on one occasion to talk of a 'Faustian' project); the overt attempt by industrialists to influence its policy; and the appointment of the neo-Marxist Jürgen Habermas as co-director.

Doubts later grew about the efficiency of the institute, which seemed to be concentrating on isolated projects. Even though one or two noteworthy pieces of work were done, the commissions, set up as a rule four years before the retirement of an institute head, started to discuss the end of the institute in its existing form. After intensive discussions the MPG Senate decided not to continue the work of Herr von Weizsäcker after his retirement "since there is no one to replace him".

Instead, a new MPI of Social Sciences is being set up, which will have four departments and according to Professor Reimar Lüst, President of the MPG, who was talking during the MPG's general meeting in Mainz last month, "is advancing no sweeping claim for the social sciences, any more than would an Institute of Physics or Biology in our society". Ralf Dahrendorf, at present Director of the London School of Economics and Political Science, was appointed as an additional director with Jürgen Habermas. Two more departments are envisaged for a political scientist and a psychologist.

Klaus Höpfner

# Soviet scientists visit UK and 'sell' technology

"SCIENCE is universal because it strives after universal truths that can be universally verified. Scientists have no option therefore but to collaborate and have done so successfully even when political relations are bad. But technology is different; because it is 'sensitive'."

So said Professor J. Ashworth, Senior Scientific Adviser to the Cabinet Office at the opening last week of the "Days of Soviet Science and Technology" organised in association with the USSR National Exhibition at Earl's Court, London. By this criterion, it might be deduced, both from the exhibition itself and from the composition of the scientific 'touring team', that détente is alive and flourishing. For both are strongly orientated towards technology.

For the exhibition, this may be inevitable; a Soyuz space-capsule or non-polluting oil refinery is much easier to demonstrate to the public than the latest developments in quantum mechanics. Even the announced "massive" participation of the Soviet Academy of Sciences, apart of course for the baby mammoth, reduces to a few technological exhibits—some special industrial alloys, a method of shaping high-precision tools from graphite and then converting them to diamond, and a laser landing system for aircraft which, Academician Basov, the leader of the scientific delegation urged, would be particularly suitable in the British climate.

Basov, who holds a Nobel Prize in physics for his work on lasers, has become, in the context of this tour, virtually a salesman for Soviet laser technology. Even addressing the Royal Society, his subject matter was more practical than theoretical—laser welding, laser precision systems for wire manufacture, laser coagulation for eye-surgery, a laser-based 2,000-line TV set in the "nearest future", as well as the prospects of lasers in the  $10^3$ – $10^6$  J range and a "very promising" hybrid reactor with a "thermonuclear target surrounded by fissile material". The main problem with the latter, he said, will be the "service life but ideologically we are prepared for further developments".

Equally a "salesman" but with longer aims in view is Professor Andrei Kapitsa, whose speciality is remote sensing from space. This he sees as a major field of potential cooperation, particularly in "global problems" such as pollution. "Even a country as large as the Soviet Union cannot save the problem of air pollution", he said. "This can only be done on an international basis." Then, too, there are problems of induced climatic change.

A major irrigation or rain-making initiative by one country could have disastrous consequences for another, if there is no international consultation. According to Kapitsa, however, Soviet planners "don't yet use space data directly, but only at the second or third remove." Science, he said, "is always two steps ahead, giving the economy a tug!"

The "Days of Soviet Science and Technology" are presumably designed to give a similar "tug" to British-Soviet economic cooperation. "Economic cooperation goes very closely with such things as know-how", Kapitsa explained. "Know-how is sold, and know-how is science".

Several members of the delegation, however, saw the "Days" rather as a useful chance of pursuing their own research. The three Medical Academicians, Kochetkov, Loginov and Puchkovskaya all spoke in terms of existing cooperation. So did Academician I. M. Kolotyrkin, who explained that in his particular field—metal corrosion—the UK and USSR have already achieved a *de facto* division of labour. "Britain is doing some very interesting work on the metallurgical side", he said, "stress corrosion, cracking and so on. In the Soviet Union we use mainly a chemical and radiochemical approach. This is a genuine sharing of effort".

For Professor F. V. Sapozhnikov, however, diverging priorities between the UK and the USSR might well have made fruitful discussions difficult. For as Deputy Minister of Power and Electrification, he is committed to a major nuclear power programme, which includes not only power generation, but even the production of hot water for district heating from small reactors sited on the outskirts of cities. (It is considered sufficient for

safety if a zone 3 km in radius round the reactor is kept free from residential use, although it may be used for agriculture, industry or leisure purposes).

The commitment to nuclear energy was well represented at Earl's Court; exhibits included a scale model of the BN-600 water-water reactor intended for the third set of the Beloyarsk power station and a diorama of the South Ukrainian power complex, which will be based on  $4 \times 1,000$  MW nuclear generating sets, with a 1,800 MW hydroelectric auxiliary plant for peak hours and a 380 MW pumped storage system.

Sapozhnikov did not see Britain's current disenchantment with nuclear power as any barrier to cooperation. "We pay a great deal of attention to UK experience", he said. "We have enjoyed a good cooperation programme for several years now, and it has worked quite successfully".

Such remonstrances have in general been fairly infrequent. Apart from the constant stress that exchange benefits the UK as much as it does the Soviet Union, there has been little emphasis on "misunderstandings" and much on mutual benefits and the building of what Basov called "a bridge of confidence" between Soviet and British scientists.

"Our main task is to learn what others have done and to show what we have done", Basov explained. Then, doubtless not unaware of the possé of demonstrators who had dogged the delegation with their banners demanding the release of Orlov, Shcharanskii and Kovalev, he added, "We respect and treat with understanding the customs of your country. As the Russian proverb says 'When you arrive at a strange monastery, don't try to induce your own rules there';"

Vera Rich

## Soviet progress in wind and solar power

SOVIET solar energy enthusiasts may one day give a new meaning to the term industrial plant. Recently Dimitri Zhimerin, Deputy Chairman of the USSR State Committee for Science and Technology, said that "scientists believe that solar energy could be used for industrial applications if generators were developed imitating photosynthesis". So far, however, no-one has announced artificial photosynthesis as a viable method.

Zhimerin's statement, however, came in an otherwise factual account of research into solar and wind power in the Central Asian Steppes. In addition to solar heating for domestic use considerable progress, he said, has been

made in water desalination for state cattle farms. Here the breakeven point occurs when water would otherwise have to travel 35–40 km.

Extensive use of solar energy in these regions could, he said, save the Soviet economy 15–20 million tonnes of conventional fuel per year while wind energy, properly exploited, could produce  $11 \times 10^6$  MW, 50 times the total capacity of all Soviet power stations in 1976. According to Zhimerin, the first wind powered electrical generator with a capacity of 100 kW was built in the Soviet Union in 1930. The experience gained with it has led to the development of "wind powered units, both mechanical and electrical". □

**CO<sub>2</sub> increased by 1.5 p.p.m. in atmosphere last year:** The US National Oceanic and Atmospheric Administration reported that the average carbon dioxide concentrations in the earth's atmosphere rose to 335 parts per million last year, an increase of 1.5 parts per million from 1977, and of 21 parts per million—or 6.3%—since 1958. A spokesman for the agency said that the increase was principally due to increasing emissions of carbon dioxide from the burning of fossil fuel. Despite the increases, however, government scientists still believe that they have several years in which to decide whether the effects of the carbon dioxide build-up warrant restrictions on the burning of coal, to which the US is increasingly turning as an alternative fuel to oil.

**Iran says no to nuclear power:** The revolutionary government in Iran has cancelled all plans for nuclear power plants in the country including two contracts for plants already under construction. The head of Iran's atomic energy organisation, Fereidun Sahabi, said the contracts with France and Germany should be cancelled for "political, economic, social, human and technical reasons". The German plant is 80% complete but overspending of £1.5bn would mean that the final cost of £3.5bn for the plant would be more than twice the international standard. "It is true that work conditions in Iran are different than in Germany, but they are not that different", said Sahabi. An Iranian energy expert, formerly in favour of nuclear energy, has prepared an analysis showing that the plants cooling towers could be used as grain silos. The nuclear cancellations are only part of a massive reorganisation of Iran's economy.

The *Financial Times* estimates that multinational losses in Iran amount to £18.6bn in the civilian sector with an equal amount in the military sector, a level of loss "unprecedented in business world wide short of a natural disaster or a global war". US and UK firms have been hardest hit because of their heavy involvement in the sale of military equipment to the Shah. The rise of workers committees in the factories has been instrumental in the cancellation of many contracts.

**Meteorologists approve world climate programme:** The executive board of the World Meteorological Organisation at its 8th World Congress on 26 May passed a basic programme of research into the world's climate. The programme will collate data from WMO's World Weather Watch initiated eight years ago and data acquired from the climate programmes of member countries in order to assess climatic change and variability with special reference to predictability and human interference. This study will be carried with the International Council of Scientific Unions. In addition, a study of the impact of climate on human activities will be carried out in collaboration with the United Nations Environment Programme. Two other projects will be a new typhoon operational experiment in the Western Pacific with special attention to hydrological effects inland and a West African monsoon experiment. There will also be an increased emphasis on training programmes in Third World countries to be carried out with money from the UN Development Programme.

*from Peter Collins in Geneva.*

**USSR asks US to halt space shuttle programme:** The Soviet Union has asked the US to halt work on the space shuttle programme, which it sees as a possible threat to its own satellites, according to a report which appeared last week in the *New York Times*. The demand is said to

have come up during preliminary discussions on ways of eliminating the spread of so-called killer satellites, which are designed to locate and destroy other craft in orbit, such as surveillance and communications satellites.

The space shuttle, which has been developed by the National Aeronautics Administration for both civilian and military purposes, is due to be launched at the end of the year. It will be used to launch military satellites into orbit, but US officials deny that there is any intention of using it for anti-satellite activities. The Soviet Union has maintained, however, that the shuttle could threaten its satellites, and has therefore asked the US to halt the testing programme. US officials describe the request as "totally unacceptable" and feel that it rules out the possibility of an early agreement on killer satellites, which they had hoped to reach before the signing of the SALT treaty by President Carter and Mr Brezhnev in Vienna on 18 June.

**Hundreds arrested, one killed in worldwide nuclear protests:** A weekend of militant anti-nuclear activity was marred by the killing in Spain of Ladi de Estan Terrane, 24, who was shot in the head during a police charge on an anti-nuclear rally in Tudela in the Basque country. The killing provoked three hours of street fighting between demonstrators and police. Anti-nuclear demonstrations also drew large numbers of people in the Netherlands, Japan, the UK and West Germany. In Canada, five sky-divers jumped into forbidden territory at the world's largest nuclear plant under construction in Darlington, Ontario and 56 others were arrested at the plant owned by Ontario Hydro. In the US over 600 people were arrested in demonstrations at plants in 12 American states. In Inola, Oklahoma 339 demonstrators braved a biting rain to get arrested by climbing the fence guarding the construction site of the Black Fox nuclear power plant.

**Test ban critic to head weapons research laboratory:** The University of California announced last week that Dr Donald M. Kerr, currently a deputy assistant secretary in the Department of Energy, has been appointed the new director of the Los Alamos Scientific Laboratory in New Mexico, succeeding Dr Harold Agnew who resigned earlier this year. Dr Kerr worked at Los Alamos, which carried out a large proportion of the US basic research into new nuclear weapons, for ten years before moving to Washington. He became the focus of some controversy last year when he opposed President Carter's proposals for a five-year test ban treaty, claiming that a treaty of such length would raise questions about the reliability of weapons that were being stockpiled but not tested.

Mr Kerr's previous involvement in weapons research is likely to lead to renewed pressures at the University of California for the university to divest itself of the Los Alamos and Lawrence Livermore laboratories, which it manages on a contract basis for the Department of Energy. Last month, an advisory committee recommended to the Department of Energy that it should prepare contingency plans, in case the university pulls out.

**Dungeness okay:** The UK Health and Safety Executive has permitted the Central Electricity Generating Board to restart its Dungeness nuclear reactor. The reactor was shut down when micro-cracks were discovered in the welds of an expansion bellows. The CEBG claimed that the cracks were present at manufacture, have not increased during use and are not a hazard. Monitoring equipment has been installed as an additional precaution.

# This nuclear power plant is contaminated.

## India's demand for energy means it cannot be shut down

*Tarapur, near Bombay.*

Nuclear power needs to be regulated in the Third World just as much as in the West. But economic pressures in developing countries mean that safety may not always come first. Moreover, western insistence on regulation may be seen as an attempt to hamper Third World progress. Report by **Anil Agarwal**

THE accident at the Three Mile Island nuclear power plant has caused considerable concern in the developed countries. But very little has yet been said about the lessons to be learnt on the safety of nuclear reactors in the Third World. Even though volumes have been written about the problems of transferring sophisticated technology to developing countries, precious little has been published about the management and absorption problems posed specifically by the transfer of nuclear technologies to the Third World. The sole exception in this field is the burgeoning literature on the proliferation aspects of nuclear technology transfer.

In the past few years, rising costs and environmental protests have halted the growth of nuclear programmes in western countries. In 1977 almost no new reactors were ordered by the industrialised countries. During this time, it seemed as if the nuclear industry had begun to shift all its attention to Third World markets in particular, with French and West German companies indulging in aggressive selling openly aided by their governments. The prospects of large orders from Brazil, Iran and South Korea seemed to confirm this trend.

Since the revolution in Iran, however, Third World markets have received a serious blow. Iran has cancelled all the nuclear plants on order and according to unconfirmed reports, Iranian authorities—and for that matter, the Western nuclear suppliers too—may not be interested in completing the Bushehr nuclear power

plant which has reached an advanced stage of construction. Among the first set of people arrested by the Shah of Iran for mismanagement and embezzlement in his unsuccessful bid to satisfy the rising demands of his people was the then Chairman of the Atomic Energy Organisation of Iran. Since the overthrow of the Shah's government, several officials of the AEOI have left Iran leaving behind only a fledgling organisation.

Brazil's controversial nuclear programme too is running up against increasing domestic criticism largely because of escalating costs. The cost of Brazil's first power reactor, the 626 MW Angra-1, which is being constructed by Westinghouse, is now expected to be between \$850 million and \$1 billion compared to the initial estimates of \$218 million. The cost of the Brazilian-West German nuclear deal of 1975 under which Brazil was to be supplied with eight nuclear power plants of 1,320 MW each by the West German company Kraftwerk Union (KWU), has already risen from \$10 billion to \$13 billion. Industry is protesting at the projected increases in electricity tariffs. Meanwhile, US pressures have prevented the French sale of a plutonium reprocessing plant to Pakistan.

Third World nuclear programmes are, therefore, slowing down under a variety of economic and political pressures. But several developing countries nonetheless have or are planning to have significant nuclear programmes. South Korea ordered two new plants in 1978 and already has one reactor in operation, and two under construction. By the mid-1980s it expects to have eight nuclear power plants that will supply nearly one-third of its electrical needs. In nuclear terms, therefore, South Korea should become Asia's second Japan. Taiwan too is pressing ahead with its nuclear programme despite the supply problems posed by its current political difficulties. Taiwan's first power station consisting of two 636 MW units started operation in 1977 and two more large plants are expected to go into service

by the early 1980s.

The Pakistan Atomic Energy Commission has asked its government to sanction the purchase of a 600 MW nuclear plant. Turkey is expected to order its first plant from Sweden soon. Argentina already has one 319 MW power reactor in operation and another 600 MW reactor under construction. It is also expected to decide on the purchase of more reactors soon, possibly this month. Argentina is mainly considering tenders from Canada and Germany. Cuba plans to go ahead with a 440 MW nuclear reactor from USSR. Mexico has two reactors under construction which are expected to be completed by 1982. With the discovery of large oil reserves, Mexico may not be keen to go ahead with more reactors in the near future.

From all present indications, it seems that the incident of Three Mile Island has scarcely sent a ripple through those Third World countries which are keen to buy and build as many nuclear reactors as they can. Part of the reason for this behaviour is that nuclear programmes have come to be associated by developing countries with enormous political prestige. The efforts of western governments to control the spread of nuclear technologies are seen by many Third World governments as a crude attempt to monopolise a technology that is of considerable importance to the world. These discriminatory western pressures have helped to make nuclear power, as a senior IAEA official recently put it, "an immensely patriotic issue" in many developing countries and even in some developed ones like Japan. Under these circumstances, nuclear authorities in Third World countries will move very cautiously to accept safety-related arguments against nuclear power.

However, where safety *per se* may fail to move Third World nuclear authorities to ensure safest possible operation of nuclear projects, sheer economics will force them to consider all safety-related issues. Unlike the US, no developing country can suddenly afford to lose a billion dollar plant because of an accident. In some

countries, a large power plant can form as much as 10% of the electrical grid. The loss of such a plant could plunge the country into an energy crisis that could cripple its growing industry.

Once a developing country has an unsafe plant therefore these economic pressures could persuade it to continue dangerous operations. The Tarapur Atomic Power Station (TAPS) on the western coast of India which supplies power to the industrially important metropolis of Bombay can, for instance, be placed in such a category. TAPS was the first atomic power station to go in operation in the Third World. It was built on a turnkey basis by General Electric under an Indo-US agreement and commissioned in 1969. Defective fuel bundles supplied by General Electric led to widespread contamination of the plant and extremely high radioactivity levels. *Business India*, an Indian journal, recently reported in an extensive survey of India's nuclear programme: "TAPS is so heavily contaminated . . . that it is impossible for maintenance jobs to be performed without the maintenance personnel exceeding the fortnightly dose of 400 mrem in a matter of minutes. Thus the maintenance worker—who is often not an employee of TAPS—holding a spanner in one hand and a pencil dosimeter in the other, turning a nut two, three rotations and rushing out of the work area is a common phenomenon in TAPS." When asked why not shut down TAPS and decontaminate it thoroughly, a senior TAPS engineer replied: "Ideally, that should have been done in 1974 or earlier but there is such great pressure from the Department of Atomic Energy on us to produce power that we cannot shut down."

It must, however, be said to the credit of the Indian nuclear authorities, who control the best technical expertise in the nuclear field in the Third World, that they have taken considerable care to minimise the radioactivity problems in TAPS. India has a massive nuclear R&D programme which accounted for nearly one-fifth of the India government's R&D budget of Rs 3,200 million (about £220 million) in 1976-77. Despite this indigenous capability, Indian engineers had to seek the assistance of General Electric when fuel defects and related radioactivity problems first began to surface—and they obtained very little help. General Electric simply blamed them for mismanagement and lack of technical expertise. Even the US Atomic Energy Commission officials were then forced to prepare a note for Commissioner James T. Ramey in which they stated: "US manufacturers have extremely poor records of information disclosure to foreign

purchasers. Designs at times do not reflect all the regulatory items required in the US; at times design innovations are first tried by US manufacturers in overseas reactors. US manufacturers normally deal with foreign utility companies and short-cut their assistance to foreign governmental control groups (like nuclear regulatory agencies), which are sometimes in weak governmental positions." These discussions led Commissioner Ramey to emphasise that General Electric should be very careful with the nuclear plant it is setting up in Mexico. Mr Ramey pointed out to General Electric that "Mexico will have no technical back-up such as that which is available in India at the Bhabha Atomic Research Centre, and that GE should pay particular attention to assuring there is an adequate operations and maintenance staff, whether or not they have a contractual obligation to do so."

Dr Morris Rosen of the Nuclear Safety Section of the International Atomic Energy Agency has further listed several critical aspects of nuclear power plant exports to developing countries. At the time of the IAEA-sponsored International Conference on Nuclear Power held in Salzburg, Rosen pointed out that several power plants quite dissimilar to those that exist in supplier countries are being built in developing countries. For instance, he revealed that high seismicity at the site of two large reactors sold by West German vendors to Iran could result "in significant design changes in the nuclear facility; changes that influence the foundations, interface of structures, pipe requirements, supports and system components (including reactor internals). Thus, the eventual design of the Iranian facility as constructed may have some significant differences from modifications which will not have

undergone a detailed review by the regulatory bodies of the Federal Republic of Germany."

Rosen pointed out another example for which there was no reference plant—a similarly sized plant under construction in the exporting country which meets its safety requirements and therefore can be licensed. "The recent 2-loop reactor plant for Egypt, Korea, and the Philippines, is referenced to a 2-loop reactor plant under construction in Yugoslavia since 1974. This plant in turn had been referenced to an earlier 2-loop plant under construction in Brazil, which in turn had been referenced to a domestic plant in Puerto Rico. However, the review of the Puerto Rico plant was terminated in late 1972 . . . and it was determined not to continue with the project. If the Puerto Rico plant had been constructed, it would have undergone a systematic and detailed review by the US regulatory organisation and as a result of this review . . . a number of modifications would undoubtedly have been made. Thus, all of the previously mentioned exported 2-loop plants have undergone a rigorous regulatory review, and modifications that might have been required are not available for consideration."

The prime need of developing countries with nuclear programmes is strong and competent regulatory agencies—unfortunately something they very much lack. In the words of Mr Rosen: "At the present time, with little exception, the regulatory organisations of developing countries with active nuclear programmes can be classified as sub-minimal. In many cases they consist of less than 15 full-time staff members associated with nuclear power activities. This minimal staff may not be familiar with the disciplines of nuclear safety and may

South Korea: first steps into nuclear power, 1974.

be in need of extensive training."

Without good regulatory agencies, developing countries can neither ensure they are being sold safe nuclear systems or that they are being operated safely. There are several obstacles to the setting up of a strong regulatory agency in a developing country. First of all, nuclear power is such a sensitive issue politically that few governments would risk setting up an organisation whose main responsibility would be to make critical reviews. Second, there is the question of cost which can be relatively very high for a small one- or two-reactor country. Third, there is the lack of technically qualified personnel.

To minimise their expenditures on nuclear programmes, most Third World governments hold the budgets of their regulatory agencies at very low levels both in foreign and local currencies. South Korea is a typical example. The Korean authorities have been making use of foreign consultants for their nuclear regulatory programme. Two separate studies have been completed, including one which gives detailed recommendations for the organisation of the regulatory body. But the South Korean government has still not put up the funds for implementing the recommendations. South Korea has also had an IAEA mission for evaluating site and safety reports. Though such procedures are useful, IAEA officials themselves do not consider them a substitute for a good domestic regulatory organisation. Like those of South Korea, regulatory units in Taiwan, Philippines and Mexico are also very weak.

At an IAEA-sponsored symposium on problems associated with the export of nuclear power plants, representatives of the Mexican Instituto Nacional de Energia Nuclear pointed out that the Mexican "regulatory body is still considered to be working under less than ideal conditions. For example, licensing actions have been taken with insufficient information and the construction schedule is such that in some cases INEN has had to make certain judgements without evaluating all the relevant safety considerations."

The Mexican case is particularly interesting as Mexico obtains its nuclear fuel through the IAEA and therefore agrees to comply with the applicable IAEA safety regulations. IAEA missions have visited the Laguna Verde Nuclear Project and identified several deficiencies. But little action has been taken. The paper quoted above points out: "Subsequent IAEA missions reported that little attention had been paid to previous recommendations. The Agency's Director General issued a second letter to Mexico's Ambassador to the United Nations. This letter was

*Western technology meets eastern architecture: Pakistan's nuclear institute at Islamabad.*

much more critical than the first one; however, the authors are not aware of the response to the letter nor of the actions taken by the Mexican government as a consequence."

The IAEA has a similar agreement with Yugoslavia but there the regulatory body is practically non-existent. A nuclear plant is under construction at Krsko with costs being shared by the republics of Croatia and Slovenia. Neither of them are interested in setting up a regulatory agency, nor are the federal authorities because of the considerable independence granted to the republics under the country's constitution. Perhaps the regulatory situation will improve when Yugoslavia becomes a two-reactor country. In India, there is considerable domestic competence, but the Atomic Energy Commission is both utility and regulator.

The IAEA's Director General, Dr Sigvard Eklund, invited a group of international experts to Vienna at the end of last month to discuss the safety issues thrown up by the Three Mile Island incident and the manner in which the agency should respond to them. The agency is currently preparing under its Nuclear Safety Standards (NUSS) programme, about 50 books in the form of Codes of Practice and Safety Guides. These will certainly help regulatory agencies in the developing countries to insist upon at least minimum requirements for safe operation of nuclear plants. But given weak regulatory bodies they will clearly have a limited impact.

An important activity that the agency could undertake is to send more safety missions to help IAEA member-states and possibly set up a system by which the agency could inspect power reactors. If the member-states of the agency were agreeable, there could be a resolution at the Board of Governors that they will adhere to the safety regulations stipulated by the agency or there could even be a specific international convention.

It is, however, doubtful whether

many Third World governments will react very favourably to such suggestions. They could be easily interpreted as yet another attempt by western governments to control the development of nuclear power in the Third World. A simple compromise like making IAEA recommendations only advisory and not mandatory could be a solution. But if countries lack the political will to ensure maximum safety or possess systems in which the utility is politically far more powerful than the regulatory agency, then regulatory work can turn out to be only a lot of paper work. IAEA safety missions could expect a considerable degree of hostility.

The inspection-related issues are likely to be discussed further at the meeting of the IAEA's Board of Governors later this month. The least that the agency could do is to step up the flow of information amongst member-states about nuclear mishaps which would help to spread understanding about how to cope with them. The Three Mile Island accident did show that proper training of operators is a matter of vital importance.

An activity that the IAEA is planning to undertake soon is the organisation of an emergency assistance system in the case of major nuclear mishaps. This would mean maintaining an international roster of experts on immediate call. The IAEA's nuclear fire-fighting brigade will, however, not be easy to operate. Experts will have to be flown from various parts of the world which will take a considerable amount of valuable time. Nonetheless, such a system will be a step in the right direction. In the TMI disaster, experts were required for several days.

In spite of international actions, the mishap at the Three Mile Island means that Third World governments with nuclear programmes will have to be more concerned with safety—and developed countries will have to ensure that safe technologies are transferred, especially to places where technical skills are still lacking. □

# How Ghana cleaned up on soap but failed with nuts and bolts

In the last of his series, **Joseph Hanlon** looks at African attempts to turn 'appropriate technology' into small industries.

SCIENTISTS and technologists anxious to make a contribution to Third World development have in recent years often turned to 'appropriate technology', where there is a real need for science and engineering input. Several universities have set up AT centres, and one of the most successful—measured in terms of technology actually put into industrial production—is the Technology Consultancy Centre (TCC) at the University of Science and Technology in Kumasi, Ghana. But the TCC's experience shows that despite the need for scientific input, the key questions are not technical. Despite its success by the standards of other AT centres, the TCC is increasingly worried about its lack of impact in Ghana, and is implicitly raising questions about the whole concept of university AT centres.

Windmills always seem to be the first project that AT centres try: they seem such a nice, small, decentralised energy technology—just what the people 'out there' need. But there are no windmills at TCC. "People who have whole research programmes into windmills ask us why we don't have a windmill project. I ask where the application is—no one has ever come and asked us for a windmill," explains Dr John Powell, TCC director. The basis of TCC is that it "very seldom comes up with its own ideas. If you go to people and say 'You should do this', then when you go away nothing happens. But if they come to you, there is a faint chance it may happen."

This philosophy has led directly to the TCC successes. The first came just after the centre began in 1972. A local man, Mr Baffoe, who made laundry starch from cassava, came to the centre to ask about making paper glue. Schools traditionally make their own glue from cassava starch and the ash from plantain peel. (Plantain is a local banana-like food which is very common.) But the glue has a very short life and is not rewettable. Baffoe was passed on to Dr Rao in the university chemistry department, who found a non-toxic fungicide to use as a preservative, and chemicals for rewettability. Baffoe began making the 'spider glue' in the courtyard of his compound, and within a year was a fairly rich man.

The glue is an ideal example of appropriate technology. It is made almost entirely from local materials and replaces an imported product. Baffoe was able to supply most of Ghana's paper

glue needs, saving considerable foreign exchange, and his glue cost less than imported glue on the local market. Furthermore, it was small scale, used labour instead of capital, and it required some scientific input.

TCC's biggest success to date has been with soap making. Soon after the TCC opened, local small scale soap makers came to the TCC asking for help in improving the manufacturing methods. Engineering and chemical analysis produced an improved formula. With £10,000 from the Ghana government, work began on improved soap making tanks. The TCC committee, composed of two engineers, a pharmacist, and a chemist, "wanted a mini Lever Brothers," Powell said, but after much discussion, the committee was talked out of advanced technology and tanks using electric kettle elements were made. They "worked well with professional supervision on the campus. But it proved too sophisticated for rural soapmakers. I would expect that now, but didn't then—it was our first big project."

With help from the Intermediate Technology Development Group (ITDG) in London, G. Prakash, a consultant on small scale soap making at the Appropriate Technology Development Association in Lucknow, India, went to the TCC. He immediately redesigned the tanks to make them easier to control, and converted them for use on wood fires. Not only was it easier for the rural soapmakers to operate, it was a better technology—both capital and operating costs for the wood fired plants were less than half those of the electric plants. The project has been a considerable success, probably the biggest of any university AT project: more than 100 soap making tanks of TCC design have been made.

The soap is produced from palm oil and caustic soda. Within a few months of the first plant opening, however, caustic soda began to run short, and TCC turned to the chemical engineering department for help. There was an acetylene plant in Tema which imported calcium carbide and reacted it with water; the waste product, calcium hydroxide was simply dumped outside the gate. This could be reacted with sodium carbonate, which still has to be imported, but at half the price of the final caustic soda. So a simple electrically heated, mechanically stirred plant was built which produced caustic soda

for less than the market price. Six are now installed. Shortages of oil for soap making led to involvement in oil palm plantations, alternative oil seeds, and improved oil presses.

TCC is now a major operation, with 80 staff and a £100,000 per year budget. More than half that money comes from TCC's own production units, which manufacture soap, nuts and bolts, and equipment such as the soap making tanks.

Its biggest project to date is a pyrolytic converter to make charcoal, gas, and oil from the sawdust available in abundance from the sawmills around Kumasi. If wood is burned by the traditional charcoal burners, the charcoal produced amounts to only 10% of the original weight of the wood. By carefully controlling the burning temperature in the pyrolysis process, it is possible to produce 25% by weight of charcoal, plus 10% oil. No fuel input is required since the output gas is used to dry the sawdust, and the burning wood provides its own heat for pyrolysis. The Ghana Government, USAID, and the Georgia Institute of Technology have all helped in what is a quite sophisticated project—temperature must be carefully controlled, and there are special problems because the density of hardwood dust is different from that of softwoods used in this system elsewhere. Nevertheless, a pilot plant on the UST campus is already processing more than 1 tonne of sawdust a day and has reached 22% charcoal and 7% oil.

From the platform of these successes, Powell and others at TCC are now raising some questions. They point out that appropriate technologies can be surprisingly marginal. For example, there is a controlled price for soap, and when rocketing palm oil prices made it uneconomic to produce soap at the controlled price, the government gave a subsidy to Unilever, but not to small soap makers. Eventually, TCC and other soap makers had simply to ignore the controlled price. Similarly, several TCC projects depend on small imported items such as bearings and colourings that are simply smuggled in because import licences are not available.

Animal feed production from brewers spent grain is a case in point. Grain left over from brewing ferments within a day, and Kumasi Brewery throws away 100 tonnes a week. The Department of Biochemistry at UST analysed the grain for a local entrepreneur and found it suitable as an animal feed (a common use of spent grain in other countries). TCC developed an effective drying process, involving a press and sun-drying, and the entrepreneur was soon in business. The nearby Guinness Brewery bought a highly mechanised drying plant at about the same time.

This runs at a loss, despite charging 6 cedis a bag for dried spent grain, while the local entrepreneur with his simple technology makes a profit at 4 cedis a bag. But he is surviving in business only because the Kumasi Brewery has consistently been refused import licenses for machinery like that used by Guinness. But how long will that continue?

The successes of TCC, however, only make clear its biggest failure. "Contrary to expectation, entrepreneurs have been very slow to follow the lead given by the university," comments vice chancellor E. Bamfo Kwakye, a strong backer of TCC. He thought that entrepreneurs would take things out of their hands, as with soap and glue, but this has not happened. Many products, such as nuts and bolts, are still manufactured on campus. There seem to be three reasons—the location of TCC, the nature of Ghanaian entrepreneurs, and economic factors.

Many small businessmen are unwilling to come to the large university campus outside Kumasi. So TCC has decided to go to them. It proposes two Intermediate Technology Transfer Units in the middle of existing informal industrial areas. These would actually manufacture products, but they would also provide training, designs, and other help to upgrade existing craftsmen. One unit will be in Suame Magazine, Kumasi, Ghana's largest informal industrial area, which has thousands of craftsmen, like fitters and carpenters. The unit there will be involved in blacksmithing, carpentry, and so on, and will have its own machine shop. The second unit will be in Tamale, in the north, and concentrate on the manufacture and repair of agricultural equipment. Funding will come from the US and Canada.

The second problem is a lack of Ghanaian industrial entrepreneurs. Ghana is well known as a trading country. It has large markets, and every family seems to have one member involved in trading or transport. This may be part of the colonial heritage—the British saw Ghana as a source of raw materials and a market for manufactured products, but they were rarely directly involved in the internal economy, as in their other African colonies. Local people were encouraged to trade, but not to manufacture goods which might compete with Britain. Trading requires different skills from manufacture, resulting in a dearth of industrial management expertise in Ghana, and this is one factor cited as a reason to opt for advanced technology, which requires fewer managers than decentralised AT. In any case, Ghanaians find trading much more pleasant—trips and chats are part of the work, the hours are flexible, and

TCC's pyrolytic converter: sawdust is burned in the tank and the gases condensed in a water collar to produce oil. Left is TCC director Dr John Powell.

profits can be very high. Industrial work, on the other hand, is physically hard, much steadier, and often noisy and dirty.

The third problem is economic. As Sally Holtermann, an economist who recently studied TCC for the Intermediate Technology Development Group in London, points out: "in an economy where the activity is to be carried out by private enterprise, entrepreneurs are not going to invest in plant and equipment that is not going to yield them a profit." Sometimes Powell recognises this. But he also told me: "You can get awfully confused with economics. Sometimes I think it is better to avoid economics and concentrate on technology."

The result is best shown by nut and bolt making. Because of import restrictions, craftsmen in Suame Magazine were having trouble getting coach bolts for the wooden bodies they make for passenger lorries. So the TCC imported some used equipment, including capstan lathes, and set up a shop on campus making nuts and bolts. It seemed an obvious technology to transfer—but it hasn't been, for reasons now becoming clear. The market is dependent on import restrictions, since imported nuts and bolts, when they are available, are one-third the price of those made at TCC. Second, making one-off motor spares and machine parts is just as profitable for the entrepreneur with this machinery, and much more interesting than long production runs of bolts. And third, TCC found out only last year that for four years its nut and bolt shop has been losing money. It now makes a profit, but not enough to interest a Ghanaian businessman.

The response of TCC has been to question the attitude of the Ghanaians. "If a nation is ripe for development, it will go forward, no matter what the development technology. India and China have reached this psychological take-off point, but it hasn't happened

here," Powell argues. "The average Ghanaian trader, if he can't make his profit today, isn't interested. Few people here realise that development does not take place overnight—you have to work for your children's children." The answer is not that simple, though. Could it be that Ghanaians are suggesting in practice that although a technology meets academic definitions of 'appropriateness,' it may not be right for Ghana?

TCC has received strong official backing. It was even mentioned in the government's last five year plan. But it has had little contact with government research and development units. It gets strong backing from the university, and practical support from a few people like Kwakye. But there is virtually no participation from other Ghanaians at the university. Nearly all of its work is done by expatriates at the university, or by Ghanaians actually on the TCC staff, some of whom are extremely dedicated. Even Powell mentions the almost complete lack of student interest in TCC. Nor have TCC's successes increased involvement; in fact, the opposite has occurred. After the success with spider glue, many faculty members refused to cooperate because they felt they were being exploited. And at the centre itself, it is the strength of expatriate Powell that keeps TCC running. People may come in at 7.30 each morning when he is there, but they don't when he is on leave.

Powell himself may have the answer. "AT will only work when it is done as in India—by people for themselves. Here, it's not Ghanaian professors working for Ghanaian peasants. The whole thing is an expatriate activity, an oboroni [white man's] hobby. I don't have to use the soap made in my factories. It's technology for them, not for us." But when the other alternative is Unilever, perhaps all Ghana can do is choose between different oboroni technologies. □

## Fibronectin: a function at the junction

from Clive Lloyd

THE fact that suspended tissue cells attach and flatten on suitable surfaces is not only experimentally convenient but a powerful example of the trans-action between internal musculature and the external environment. Involvement of the cell's actomyosin system in making contact and generating movement began to emerge some time ago and now there is evidence to promote the involvement of the extracellular molecule, fibronectin (also known as LETS protein), in forming organised cell adhesions. The significance of these recent findings is that fibronectin and associated extracellular proteins—perhaps in a process common to many biological events—stimulate the formation of cytoplasmic organisation. This raises questions about the nature of the transmembrane steering linkage between the two systems.

At the observational level tissue culture cells which are spread on a culture dish become spheroidal when brought into suspension but will flatten once more when restored to some suitable surface. At the molecular level, this cycle of events can be described in terms of the development of the internal musculature by which a cell grips the substratum (Rees *et al.* *Nature* **267**, 124; 1977) and then the loosening of this grip (and hence the loss of asymmetrical cell shape) in the presence of dissociating agents. Components of this actomyosin system can exist in different states of organisational complexity (see Lazarides and Revel, *Sci. Am.* May 1979, for a graphic account) but conspicuous microfilament bundles which characterise and maintain the well-spread cell often seem to 'crystallise' out from localised points of cell-cell or cell-substratum contact. Because not all surfaces support active cell spreading, the nature of the congenial substratum is clearly important in setting up microfilament bundles and this is where fibronectin seems to play a major part. For instance, transformed cells deficient in microfilament bundles,

spreading ability and cell surface fibronectin (LETS) can be converted back to a more normal spread morphology with abundant microfilament bundles by the administration of fibronectin (Willingham *et al.* *Cell* **10**, 375; 1977; Ali *et al.* *Cell* **11**, 115; 1977). Conversely, the dissociating agent trypsin, at low levels, removes LETS from the cell surface (Hynes *Proc. natn. Acad. Sci. U.S.A.* **70**, 3170; 1973), perturbs the organisation of cytoplasmic microfilament bundles and converts well-spread cells into rounded ones (Pollack and Rifkin, *Cell* **6**, 495; 1975). The distribution of fibronectin is consistent with its role in cell attachment for it can occur as a fibrous meshwork sandwiched between the cell and the substratum and is also observed between cells in contact (see Yamada and Olden *Nature* **275**, 179; 1978 for general review).

These general properties are an already accepted chapter of the fibronectin/LETS saga but a more detailed examination of the correspondence between this extracellular molecule and the cytoskeleton will be required before any reasonable molecular explanation of their relationship emerges. Towards such an explanation, Hynes and Destree (*Cell* **15**, 875; 1978) used double-label immunofluorescence to tackle the problem. They show that actin microfilament bundles close to the cell's substratum are often (but not always) co-extensive with fibronectin outside the cell because the rhodamine anti-fibronectin and fluorescein anti-actin image are, to a reasonable degree, superimposable. The resolution of this technique is suggested to be not greater than 200 nm, but still more recent evidence suggests that any transmembrane gap between these parallel systems of fibres (if one exists at all) is of the order of 8–22 nm. I. I. Singer (*Cell* **16**, 675; 1979)

reported electron microscopy of thin sections cut through regions where internal microfilament bundles and external fibronectin-containing fibres meet, proposing that the electron-dense plaque where the two systems come together be called the fibronexus. Sections cut approximately parallel to the plasma membrane gave the appearance of microfilament bundles overshooting the plasma membrane and continuing on through the extracellular space—a conclusion that Perdue (*J. Cell Biol* **58**, 265; 1973) had previously reached by an electron-histochemical study of chick fibroblasts. With the benefit of ferritin-conjugated antibodies to fibronectin (probably not available to Perdue at that time) Singer shows that the extracellular portion of this transcellular highway contains fibronectin. This agrees with Hynes and Destree's observations that "actin microfilament bundles frequently terminated before the periphery of the cell, whereas the co-linear fibronectin often continued further towards the edge of the cell and even beyond it". Singer tilted his sections through 40° in the electron microscope to see if there was any hidden gap between the two systems but, given the limits to resolution, he saw none and the structures remained co-linear throughout. This tends to suggest that where fibronectin and microfilament bundles are related, they are related in a 1:1 manner, but whether this relationship is co-axial or of overlapping ends with some special binding structure in between, is an open question. The fibronexus, then, would seem to be synonymous with cell adhesion plaques except that a role for fibronectin in forming such junctions is now more clearly claimed.

The recent paper of Thom *et al.* (*J. Cell Sci.* **35**, 281; 1979) bears directly on this and concludes that fibronectin is necessary for the formation of organised junctions, but not entirely sufficient. Interference reflection microscopy is a technique that

Clive Lloyd is with the Biosciences Division of Unilever Research, Bedford, UK.

produces a contour-map of the under-surface of the cell—the focal points of close contact with the glass ('feet') being darker than more distant areas of the cell body. These 'feet' are known to be the terminations of microfilament bundles (Heath & Dunn *J. Cell Sci.* **29**, 197; 1978) and in the electron microscope they have a structure resembling half of an intercellular junction of the adherens type (see Heaysman, in *Locomotion of Tissue Cells*, Ciba Symp. No. 14, 187; 1973). Thom *et al.* demonstrate that a line of rat fibroblasts attaches and spreads on glass pre-coated with fibronectin isolated from chick serum but that the interference reflection image of 'feet' remains poor and not fully organised unless other components of serum are also present.

Such other components may therefore either directly participate in the organised adhesion or may merely maintain the cell until it can tailor its own fibronectin into more favourable arrangements than occur adsorbed onto pre-coated glass.

As for the internal face of the junction, Singer echoes the view that the fibronexus may be the nucleation centre for actin bundle formation, quoting Lazarides and Burridge's observation (*Cell* **6**, 289; 1975) that the Z-band protein of skeletal muscle ( $\alpha$ -actinin, which holds actin thin filaments in ordered arrays) is also present at the termini of microfilament bundles in non-muscle cells. In keeping

with this are Geiger and S. J. Singer's findings (*Cell* **16**, 213; 1979) that various specific extracellular ligands cause receptors to accumulate into patches and caps on the surfaces of various cells at the same time that  $\alpha$ -actinin forms sub-caps at the cytoplasmic face of the membrane. Inferences to be drawn from this include the possibility that  $\alpha$ -actinin provides the hinge between actin and integral membrane receptors, or that  $\alpha$ -actinin may collect together actin-linked receptors. This takes on further shape for adherent fibroblasts in Badley *et al.*'s recent work (*Expl Cell Res.* **117**, 231; 1978) in which cell bodies were removed from glass by a stream of buffer, leaving 'feet' behind in the same pattern as they existed in the intact cell. All of the components discussed so far in terms of a trans-membrane assembly could be detected by immunofluorescence at these adhesion plaques: actin, myosin, tropomyosin,  $\alpha$ -actinin, LETS (but not tubulin or serum albumin).

Putting all this together, fibronectin is a sticky protein which agglutinates red blood cells (Yamada *et al.* *Proc. natn. Acad. Sci. U.S.A.* **72**, 3158; 1975); has a binding site for collagen (Hahn and Yamada, *Proc. natn. Acad. Sci. U.S.A.* **76**, 1160, 1979); may be closely associated with sulphated proteoglycans (Perkins *et al.* *Cell* **16**, 941; 1979) and may therefore help organise biological matrices. It is concentrated at points of cell contact and can be traced

across the membrane to actin microfilament. Just as the external contact may be stabilised by components of the extracellular matrix, so the organisation at the internal face of the junction may be underpinned by  $\alpha$ -actinin. However, any communication across the membrane is likely to be two-way because external fibronectin stimulates internal microfilament bundle formation while, conversely, breakdown of the bundles by cytochalasin B (Kurkinen *et al.* *Expl Cell Res.* **111**, 127; 1978) causes the release of fibronectin from the cell surface.

Of course, there is strong evidence that the cytoskeleton can be modulated indirectly by the addition of cyclic nucleotides to cells (see Pastan and Willingham *Nature* **274**, 645; 1978) but in cases where the contractile cell flexes its muscle against the outside world (in attaching to cells and other biological surfaces, during cell migration and phagocytosis), a direct linkage is likely to be of prime importance. It has been suggested that many classes of external peripheral proteins cluster against one common class of trans-membrane protein which alone holds the hot-line to cytoplasmic microfilaments (Bourguignon and Singer, *S. J. Proc. natn. Acad. Sci. U.S.A.* **74**, 5031; 1977). The name given to this postulated molecule is perhaps an eloquent summary on the current debate about how outside and inside hinge together—it has been called 'protein X'. □

## Nucleic acid statics and dynamics

from Stephen Neidle

RECENT years have seen a revival of interest in structural studies of both nucleic acids themselves and of model systems for them. The impetus for this can be attributed to various causes—it comes from work on chromatin and transfer RNA; from visualisation of the structures of nucleic acid fragments, sometimes complexed with drug and mutagen molecules, and from the emergence of new and powerful techniques, especially the advent of high-resolution nuclear magnetic resonance spectroscopy. It was perhaps timely that at a recent meeting on 'molecular stereodynamics'\* half the sessions were concerned with such topics.

Even though hypothetical non-double-helical models for DNA are largely discounted (Arnott *Nature*

**278**, 780; 1979; Crick *et al.* *J. molec. Biol.* **129**, 449; 1979), there is lively interest in non-classical double helices. Levitt's analysis from empirical energy function calculations has suggested that in solution DNA has about 10.5 rather than 10 base pairs per turn, with the base normals markedly tilted from the helix axis and the base pairs themselves having propeller-like twists (*Proc. natn. Acad. Sci. U.S.A.* **75**, 640; 1978) D. M. Crothers (Yale) presented data from transient electric dichroism studies on drug-DNA intercalation complexes which seem to support some features of the Levitt model. In these structures, the drug chromophores are tilted by an average of about 20° from the perpendicular to the helix axis; nonetheless the nucleic acid was not observed to bend or kink *à la* Sobell (*J. molec. Biol.* **114**, 333; 1977). Such observations can only be rationalised by evoking partial unstacking and tilting of base pairs at the intercalation site. This in turn suggests a base-pair twist angle in DNA of 17°,

as does Levitt's model. L. S. Lerman (State University of New York, Albany), the originator of the intercalation concept, reported on his studies of DNA torsional elasticity probed with spin-labelled intercalators. Evidence was presented for substantial internal movement within the double helix; a single base pair oscillates about the helix axis with a root mean square amplitude of about 5°.

Nevertheless detailed structural data on nucleic acid-drug intercalation complexes (as opposed to hypothetical models), is still largely lacking. A favoured indirect approach to this problem is through the study of model systems. The pioneering crystallographic studies of H. M. Sobell (University of Rochester) on drug-ribodinucleoside complexes have clearly illustrated the intercalation phenomenon at this level. Sobell interprets these structures in terms of DNA complexes possessing kinks at the intercalation sites—this in turn has led him to suggest that DNA is a

\*A conversation on Stereodynamics of Molecular Systems was held at the State University of New York, Albany, on 23-24 April, and was organised by R. H. Sarma under the sponsorship of the State University of New York and the General Electric Company.

dynamically kinked-unkinked structure. The basis for kinking, alternating sugar pucker of residues at the intercalation site, was challenged by the results of H. M. Berman (Institute for Cancer Research, Philadelphia) and S. Neidle (King's College London), who find that for dinucleoside complexes, the nature of the sugar pucker (a parameter known to be 'soft') is probably unimportant. A. Rich (Massachusetts Institute of Technology) has also examined the crystal structures of several of these model intercalation complexes, and concludes that the expression of sugar flexibility in them depends on whether or not the particular drug involved interacts with the phosphate group in the backbone. It is not clear to what extent such drug-ribodinucleoside complexes are meaningful models for the drug-DNA complexes themselves. As Berman emphasised, great caution is needed in extrapolating from the model systems. Indeed, the data presented by Crothers suggest that the model complexes may be related to the DNA ones in rather more subtle ways than hitherto believed.

High-resolution nuclear magnetic resonance (NMR) is in principle a powerful probe of oligonucleotide conformation in solution, so as to provide data complementary to that from the crystal structures, as well as dynamic information. However, complete analyses of the spectra in terms of molecular geometry of even a relatively simple system such as a drug: dinucleoside one, have not been made. In spite of this proviso, NMR has been most useful in the study of many aspects of intercalation complexes. T. R. Krugh (University of Rochester) has shown that the simple intercalators such as ethidium show a marked sequence preference on binding, with pyrimidine-purine ones being preferred. This is the reverse of the preference shown by actinomycin D, which Krugh and his associates have shown to exhibit sometimes unexpected nucleic acid-binding behaviour. For example, although it has been known for many years that the drug requires a guanine at its binding site (and thus does not bind to poly(dA-dT).poly(dA-dT)), the anti-tumour intercalator daunomycin, which does bind to this polymer, actually creates noncompetitive actinomycin binding sites.

D. J. Patel (Bell Laboratories) has been examining by proton NMR the structural dynamics of synthetic polynucleotides both with and without intercalating drug. He presented further evidence for the 'softness' of

the sugar pucker in such systems. However, it is not clear whether, at least for an intercalative complex, the mixture of sugar conformers observed indeed represents a true alternating sugar situation (as propounded by Sobell), or a mixture of conformational populations. The power of the NMR method in conjunction with molecular model-building was well shown by R. H. Sarma (State University of New York, Albany) and his colleagues, who have examined models for the novel vertically stacked double helix suggested by Olson (*Proc. natn. Acad. Sci. U.S.A.* **74**, 1775; 1977). The concept of nucleic acid flexibility was further taken up by N. R. Kallenbach (University of Pennsylvania), who has examined the equilibrium and dynamics of transient base-pair breakage by following proton exchange rates, a simple yet powerful structural probe. Kallenbach concludes that indeed there are transient open states (analogous to Sobell's picture of DNA 'breathing').

Gleaning of dynamic properties from crystallographic results is necessarily an indirect process. However, both Rich and S.-H. Kim (University of California, Berkeley) valiantly attempted to confront this problem armed with their data from both small oligonucleotide and transfer RNA studies. Nucleic acids are inherently flexible, and tend to respond to their environments (be they drugs, counter-ions or proteins), in well defined, or at least preferred ways. It is apparent that even short stretches of double helix can easily be bent under the influence of directional ionic forces; in transfer RNA the axis of one helical stem has been observed to bend by some 25°. More controversially, Rich suggests that DNA winding around the histone core in chromatin is due to histone location on only one side of the double helix. The related problems of solvent accessibility and exposed surface area in nucleic acids were discussed by Kim, who emphasised the importance of knowing which are in fact the penetrable regions of these molecules, when considering possible interactions. By considering the Van der Waals radii of the atoms in a nucleic acid, he has shown, for example, that in (classical) B-DNA the minor groove can accommodate only very small probes. This distinctive method of looking at nucleic acids gives essentially a static picture; however Kim considers that the use of individual atomic thermal parameters as a description of motion may well lead to knowledge of dynamically accessible surface areas.

There are perhaps more distinct theoretical approaches to the prediction of nucleic acid conformation

## A hundred years ago

THE Italian State Secretary for Public Buildings has sanctioned the plans submitted to him for the construction of an observatory on the summit of Mount Etna.

THE Anthropological Exhibition at Moscow seems to be one of great interest. It is contained in a vast building lent by the Minister of War, and is used in winter for drilling soldiers, and the exhibition has been rendered as picturesque as it is scientific. A garden which has been arranged most artistically for the purpose presents, among other features, a very remarkable "palæontological valley." This is planted with lycopods, gigantic ferns, and other fossil plants; this forest is inhabited by models representing megatheriums, mammoths, ichthyosaurs, &c. On miniature mountains, the age of which is indicated by artificial geological sections, are shown *fac-similes* of Russian, French, Danish, and other tumuli. Besides this, an ethnological garden is peopled with models representing the principal human types, especially those of Russia. There is, besides, a remarkable anatomical and craniological exhibition. Altogether this is one of the most remarkable anthropological exhibitions ever brought together, and has been an immense success.

DR MICLUCHO MACLAY the Russian explorer, with an Italian, Chevalier Bruno, and Capt. Leeman, have sailed from Sydney for New Guinea, in the American schooner *Laddie*, F. Caller, chartered for a twelvemonth's cruise. 2,500*l.* has been spent on the equipment. The expedition is intended to be both scientific and commercial. New Caledonia, New Britain, and other islands are to be visited.

From *Nature* **20**, 5 June, 131, 134; 1879.

than there are actual practitioners of such arts. The experimentalist tends to treat all of them with a healthy scepticism. It was thus gratifying that S. Broyde (New York University), reporting on her semi-empirical energy calculations with B. Hingerty (Oak Ridge National Laboratory), with a model for the coil form of the poly(U) conformation, was able to show that the low-energy form suggested agrees with hydrodynamic and NMR data on poly(U). W. K. Olson (Rutgers Univer-

sity) has used the methods of polymer chain statistics in assessments of DNA flexibility dependence on chain length. Her results suggest that very small changes in just a few conformational parameters of individual residues lead naturally to very considerable flexibility in the polymer as a whole.

These contributions signify some of the more promising directions in which nucleic acid structural studies are going. All of these, however 'biological' the nucleic acid environment may be in an experimental situation can only provide *in vitro* data. One must look in the future to techniques such as those involving NMR described by S. S. Danyluk (Argonne National Laboratory), for information from intact biological systems. □

## Scrambling of Rydberg states by thermal radiation

from Peter Knight

ALL atomic systems are immersed in a bath of blackbody radiation, a background thermal field characterised by the ambient temperature of the body. For the most part physicists interested in radiative transitions of excited atoms just ignore the existence of this field, principally because the number of blackbody photons with a frequency close to the atomic transition under study is vanishingly small, so that stimulated processes due to background thermal fields are negligible. Nevertheless, if the transition frequency is small enough, the Planck distribution of thermal photon numbers ensures that stimulated emission and absorption will begin to take over from purely spontaneous radiative decay.

Recent experiments by Gallagher and co-workers at the Stanford Research Institute have indicated that transitions between very highly excited Rydberg states are sensitive to background thermal fields. At the transition frequencies that interest them, the thermal photon occupation number at room temperature can be as high as 10. The stimulated absorption and emission of this background radiation rapidly redistributes an initially excited state population among its neighbours and considerably shortens the lifetime of some states. Consequently it would seem quite difficult to observe the decay of a

single isolated Rydberg state in these circumstances: after a very short time a distribution of states rather than a single state exists.

In their first paper, Gallagher and Cooke (*Phys. Rev. Lett.* **42**, 835; 1979) report the observation of the shortening of the sodium radiative *np* lifetimes by a factor of 3 by 300 K blackbody radiation induced emission and absorption. They measured the effective lifetime of the 17p and 18p states of sodium produced by sequential excitation by two dye laser pulses driving the  $3s \rightarrow 3p \rightarrow 18p$  or 17p transitions. These states can be detected by field ionisation by a d.c. field, with a pulsed technique which allows them to monitor the time-evolution of the excited state population. Their results indicate that the lifetimes are a factor of three shorter than the calculated  $T=0$  K lifetimes, in agreement with their fairly simple analysis. They believe discrepancies between theory and experiment for transitions observed by other workers can be explained by thermal background effects. They also calculate that radiative redistribution of population among neighbouring states of different *l*-quantum number due to the thermal field can be as important as collisional redistribution. This could well have astrophysical implications. Gallagher and Cooke also calculate the a.c. Stark frequency shifts produced by the thermal field. These had, in fact, been investigated theoretically some years ago by Barton (*Phys. Rev.* **A5**, 468; 1972) and by Knight (*J. Phys.* **A5**, 417; 1972), and the results of Gallagher and Cooke are in agreement with those earlier quantum electrodynamic calculations. The thermal field shifts all the close-lying Rydberg states upwards in energy by an equal amount of the order of kilohertz. Low-lying states are shifted by a much smaller amount according to the theoretical work of Barton and Knight. So photoabsorption from a low-lying state to a Rydberg state may well exhibit temperature-dependent shifts, although these have yet to be seen. In a further paper, Gallagher and Cooke discuss the use of Rydberg atoms as a detector of 300 K blackbody radiation (*Appl. Phys. Lett.* **34**, 369; 1979), hinging on the sensitivity of field-ionisation as a monitor of highly excited state populations. They suggest that temperatures of less than 25 K could be detected by Rydberg-atom systems.

It is interesting to the theorist that the atom immersed in a radiation field is quite different from an isolated atom. The radiation bathing the atom also dresses it, so that what started as an isolated state is scrambled into a distribution of nearby states with transition frequencies determined at least in

part by the local environment. Hot atoms aren't just moving faster than cold atoms (and therefore the ensemble emitting a wider Doppler-broadened line): each hot atom is distinctly different from a cold atom in its radiative properties. □

## Proteins of iron metabolism

from Pauline Harrison and E. R. Huehns

THE main topics discussed at the recent, fourth International Conference on Proteins of Iron Metabolism\*—transferrin, the iron transport protein, and ferritin, the iron storage protein—are both in their own way still subject to considerable controversy. Transferrin has long been known to have two iron-binding sites, but whether these are identical structurally and, if different whether this has physiological importance, as Fletcher and Huehns proposed (*Nature* **218**, 1211; 1968), has been argued about at the previous three meetings.

B. Gorinsky (Birkbeck College, London) presented a '6Å resolution model' of rabbit transferrin while J. E. Abola from Pittsburgh had studied hen ootransferrin. The rabbit molecule consists of two lobes which can be described approximately by ellipsoids. The longest axes of these ellipsoids are inclined at about 30° to one another. The maximum overall dimensions of the molecule are approximately 100×50×40 Å. Both lobes exhibit clefts in the vicinity of the join. In one lobe the cleft is close to a column of strong electron density which could be  $\alpha$  helix, and on the opposite side of this lobe there is a strong feature which at higher resolution may prove to be  $\beta$  sheet. From other work it can be concluded that there is one iron-binding site on each domain and that the N-terminal binding site can be distinguished from the C-terminal one. Several investigators (J. Williams, Bristol; P. Aisen, New York; H. G. Van Eijk, Rotterdam) utilised electrophoresis in 6 M urea, as described by Seal and Mackay (*Biochim. biophys. Acta* **453**, 250; 1976), to separate the four species of transferrin—apotransferrin, diferric transferrin, and the two species of monoferric transferrin, one with iron on the N-terminal site only and the other with iron on the C-terminal site only—and to measure their distribution after the addition of iron to apotransferrin *in vitro* and in

\*Held in Davos on 17–21 April 1979.

Peter Knight is SRC Advanced Fellow at Royal Holloway College, University of London.

plasma. The results show that the distribution of iron on the two binding sites is not random both in *in vitro* loading experiments and in plasma *in vivo*. How far the results will confirm the detailed predictions of the so-called Fletcher-Huehns hypothesis has not been determined. But the non-equivalence of the two iron-binding sites and the non-random distribution of iron on them in plasma seems to be established and is presumably of some physiological importance.

An interesting approach to the evolutionary significance of transferrin was that of F. M. van Bockxmeer and E. H. Morgan (Western Australia) who compared the binding of transferrin to heterologous receptor cells and, from the relative affinities, constructed an evolutionary family tree for transferrin. Several investigators attempted to isolate the transferrin receptors from reticulocytes (J. Glass, Boston) or the placenta (E. B. Brown, Hong Kong and St Louis), but this work is still in its early stages.

Since the conference in 1977, advances have been made in the determination of the structure of the iron-storage protein, ferritin. P. Harrison (University of Sheffield, UK) described the interpretation of the 2.8 Å resolution electron density map of horse spleen apoferritin, in terms of a symmetrical arrangement of 24 equal subunits of 60%  $\alpha$ -helix content. The sequence determination is nearly complete (R. R. Crichton, Louvain-la-Neuve, Belgium) and interpretation of the three-dimensional map with sequence data is in progress. A complete description of this structure, now in sight, opens up the prospect of being able to settle arguments on how the ferritin molecule accumulates and releases its iron. Perhaps it may also lead to eventual agreement on the problem of ferritin heterogeneity, still a confused area. Differences in ferritin molecules both within and between preparations have been observed by electrophoretic and immunological methods. It now seems clear that these differences cannot all be explained by a single unifying hypothesis, such as that of J. Drysdale (Boston) who has proposed that all ferritins are heteropolymers of two subunits of different primary structure. Observations of apparent subunit size differences persist in some ferritins, although some types of reported heterogeneity may be methodological artefact. It now seems

unequivocal that ferritins from different cell types may differ in charge. For example, this was reported for ferritins from rat liver Kupffer cells and hepatocytes by J. W. Halliday (Brisbane, Australia) and from bullfrog red cells and liver cells by E. C. Theil (Raleigh, N. Carolina) who also reported amino acid composition differences.

Several workers produced evidence that iron-loading changes the 'isoferritin' pattern, but it is not clear whether this results from selective synthesis and/or degradation, or from post-translational modification. M. Worwood (Cardiff, UK) found that a fraction of serum ferritin is modified by glycosylation, a fraction which may alter in diseased states. These workers also reported that the immunological properties of circulating ferritin in patients with malignant disease are similar to those of ferritin from normal spleen. A molecule with high iron-content (significantly different from ferritin) has been found in *E. coli* grown on iron-rich media by E. R. Bauminger (Jerusalem and Rehovoth, Israel), suggesting that a means of conserving iron or of compartmentalising unneeded iron, is more widely required than hitherto recognised. On the other hand, iron-storage may not be the whole story with ferritin. Immunosuppression in patients with Hodgkin's disease may be partly linked with the presence of ferritin on their lymphocyte surfaces.

The last session of the conference concerned the management of transfusional iron overload, and although there were no new approaches, several investigators confirmed that maximal iron excretion could be best achieved using daily subcutaneous desferrioxamine with vitamin C supplements. The production of animal models of iron overload was also described by G. McLaren (Cleveland) and M. Awai (Okayama, Japan). □

## Ion-driven inertial fusion

from Richard C. Arnold

THE first experiments using pulses of light ions to implode a hollow target, which might in the future be scaled up to produce inertial-confinement fusion, have been reported (*Phys. Rev. Lett.* **42**, 610; 1979) by a group at the

Sandia Laboratories in the US.

Previous experiments have been carried out for some years with lasers and electron beams (see Stickley *Phys. Today* **50**; April 1978); thermonuclear burn has been achieved in both cases. The light ion driver experiments reported, with pulse energies of 0.5 terawatt, are as yet at least one order of magnitude too weak to produce a measurable neutron yield (in fact, no attempt was made to use deuterium or tritium), but are sufficiently powerful to allow meaningful diagnostics of target response.

Ion beams can be produced with high electrical efficiency, and deposit their energy very effectively in the metallic surface of a fusion target. In these respects light or heavy ion-beam drivers are superior in principle (compare *Sci. Am.* **239**, 50; 1978) to existing laser systems. However, the physics and technology required to arrange focusing of intense ion beams on a small target for implosion purposes has been questioned, particularly for light ions of low kinetic energy ( $\sim 1$  MV) and high currents ( $\geq 1$  MA) required for an inertial-fusion reactor. The Sandia experiments have demonstrated that a major fraction of their ions can be deposited on thin ( $\sim 4 \mu\text{m}$ ) conical target shells about 1 cm in diameter, driving the shell inward in an axially symmetrical implosion. A plasma temperature of 12 eV was achieved at the peak of collapse (thermonuclear burn in this configuration would probably require about two orders of magnitude greater temperature).

The pulsed-power technology used in these light-ion experiments is relatively inexpensive compared with the heavy-ion multi-gigavolt accelerator technology (see *Nature* **276**, 19; 1978) now under development with a view to commercial power applications. As a consequence, fusion target experiments with light ions will probably be done much earlier than in the US heavy-ion programme. The latter technology, however, has many potential advantages for commercial reactor design. For example, heavy-ion beam propagation over several meters in a reactor vessel is expected to be classical and relatively straightforward; while for light ions, such long-distance propagation must be carefully arranged through a pre-ionised neutralising plasma channel, raising serious questions of possible propagation instabilities at the low kinetic energies used. Propagation and focusing on a small spot ( $\ll 1$  cm) thus need to be demonstrated with light ions, and several groups in the US (at Sandia, Cornell University and the Naval Research Laboratory) are investigating this question. □

Richard C. Arnold is in the Heavy-Ion Fusion Program at Argonne National Laboratory, Argonne, Illinois.

## A decade of plate tectonics

from A. Hallam

J. TUZO WILSON is widely acknowledged as one of the founding fathers of the new global tectonics. Because he has been successively Professor of Geophysics and Principal of Erindale College in the University of Toronto, before taking up his present position of Director of the Ontario Science Centre, it is appropriate that the university recently held a conference\* to honour his multifarious contributions to earth science. Although various topics were discussed, including the early thermal history of the Earth, electromagnetic studies of the crust and the origin of ore deposits, the dominant theme was plate tectonics. Approximately a decade has passed since plate tectonics became generally accepted, and the meeting provided a valuable means of finding out how the subject was now being studied in a range of disciplines and of taking stock of the current state of knowledge.

Much of the critical research leading to the earth sciences revolution was in the fields of rock magnetism and seismology, and several leading workers were present to outline recent advances. Both A. Cox (Stanford University) and E. Irving (Earth Physics Branch, Energy, Mines and Resources, Ottawa) indicated how detailed palaeomagnetic studies in alliance with geological research demonstrate that extensive sectors of the Western Cordillera of North America had either rotated or been translated northward for substantial distances in the late Mesozoic and early Tertiary. While Irving was concerned essentially with northward movement of two landmasses, Wrangellia and Stikina, Cox dealt mainly with inferred rotations. To apply sailing terms, the structural geologist studies pitch and role but only the palaeomagnetist can determine the yaw. D. York (University of Toronto) showed how a combination of palaeomagnetic and isotope studies could help to unravel complex events in the Precambrian and confirm, for example, the reality of the polar wandering event about  $10^9$  years ago known as the Grenville Loop.

A quite different approach to rock magnetism was adopted by F. J. Vine (University of East Anglia) who concerned himself with the record of reversals of the geomagnetic field revealed by ocean floor anomalies, and demonstrated how further detailed re-

search could reveal information on variations in intensity of the field in space and time, which can delimit changes in the strength of the dipole and non-dipole field components with time.

Seismological data originally provided strong evidence for the delimitation and character of plate boundaries, and attention is now being directed more to seismicity within plates. L. R. Sykes (Lamont-Doherty Geological Observatory, New York) indicated that intraplate earthquakes tend to be concentrated along pre-existing zones of weakness affected by the youngest orogeny that predates the opening of the present oceans. Many such zones, marked by fault and suture lines and failed rifts, were reactivated during the early stages of continental separation. In contrast, intraplate shocks rarely occur within the older oceanic lithosphere or within ancient continental cratons.

The seismic reflection profiling method, developed by the oil industry for the study of sedimentary basins, is now being applied to the study of the structure of the continental basement. The most interesting result so far, as described by J. Oliver (Cornell University) is the discovery that the Blue Ridge and Piedmont provinces of the Appalachians are allochthonous and have been thrust at least 275 km westwards.

Appropriately enough, considerable attention was paid to the Wilson Cycle of ocean opening and closure, the principal preoccupation being the character of subduction zones. S. Uyeda (Earthquake Research Institute, Tokyo) presented a model of two contrasted types of subduction zone exemplified by the eastern and western sides of the Pacific, which was developed in more detail by J. F. Dewey (State University of New York, Albany). Flat subduction trajectories produced by flat mantle flow and/or the subduction of young lithosphere produces pervasive compressional strain in the overriding slab at high slip-rates. Steep subduction trajectories, subduction of old lithosphere and low slip-rates induce back-arc spreading. Dewey went on to argue that plate tectonics in its present form has been in operation for about  $2 \times 10^9$  yr, a view supported by P. Hoffman (Geological Survey of Canada) in his description of an early Proterozoic Wilson cycle in northern Canada.

Similarly, there was accord between Dewey and W. R. Dickinson (Stanford University) that a tectonic mosaic involving horizontal motions was already in existence in Archaean times, and the model of early continental evolution put forward by S. Moorbath (Uni-

versity of Oxford) was consistent with this interpretation. Moorbath argued strongly that isotopic data pointed to continental growth by irreversible differentiation of the upper mantle throughout geological time, rather than by reworking and regeneration of much older crust. Intriguingly enough, Tuzo Wilson was once most widely known for his notion of continental accretion, albeit at a time when he was a staunch opponent of continental drift.

Other aspects of subduction were dealt with by W. S. Fyfe (University of Western Ontario), who argued for substantial subduction of sediments, a view contested by Moorbath, and A. Miyashiro (State University of New York, Albany). Miyashiro concerned himself with metamorphism and estimated that W. G. Ernst's successive models of the high pressure—low temperature zone had greatly improved our detailed understanding, whereas serious problems remained with the low pressure—high temperature zone, notably the origin of the magmas generated there. It seems that the old, widely accepted model assuming magma generation by simple partial melting of the oceanic crust in a descending slab is no longer tenable.

A reassessment of Panagaea reconstructions and time of Mesozoic breakup was undertaken by A. Hallam (University of Birmingham). The familiar 1-km isobath computer reconstructions were inaccurate in detail because it is now known for many regions that the boundary of continental and oceanic crust must occur beneath 2–4 km or even greater depths of ocean, breakup having been preceded by extensive stretching and subsidence. Furthermore, there may be a long time interval between initial taphrogenic activity ('rifting') and creation of ocean floor by spreading ('drifting'). A. J. Boucot (Oregon State University) expressed scepticism about reconstructions of changing continental positions in the Palaeozoic and attempted to show by plotting fossil and climatically significant sediment distributions that an unchanging Panagaea was as satisfactory a model as any. On the other hand, H. Williams (Memorial University, Newfoundland) argued that geological evidence in the Appalachians supported the view that the Iapetus was a major ocean. Problems indeed remain in reconstructing continental positions in the Mesozoic and Cainozoic, but they seem to be child's play in comparison to earlier periods of time. Our best hope would seem to rest with the palaeomagnetists. □

A. Hallam is Lapworth Professor of Geology at the University of Birmingham.

\* The symposium was held at the University of Toronto on 14–16 May 1979 and the proceedings will be published as a special paper of the Geological Association of Canada.

## Quantum chromodynamics

William Marciano & Heinz Pagels

The Rockefeller University, New York, New York 10021

*There has been a growing conviction during the past few years within the high-energy physics community that a fundamental theory of the strong interaction has been found. This theory is called quantum chromodynamics (QCD) and if correct it will be a major triumph for theoretical physics. In this review we trace the experimental and theoretical developments which gave rise to QCD, outline its basic properties and discuss its successes and remaining problems.*

THE fundamental forces in nature are conventionally divided into four categories. They are, in order of their apparent strengths, strong, electromagnetic, weak and gravitational interactions. Two of these, electromagnetic and gravitational interactions, are long range and hence dominate our physical surroundings; so they are the most familiar and best understood. On the other hand, both strong and weak interactions are extremely short range (they only occur over distances  $\leq 10^{-13}$  cm), so their relevance and study are primarily limited to the disciplines of nuclear and elementary particle physics. The weak interaction is responsible for phenomena such as  $\beta$  decay of neutrons into protons and neutrino interactions with matter; in addition it violates some otherwise exact symmetries of nature such as parity and time reversal invariance. The weak interaction gained notoriety recently because of the success of the Weinberg-Salam model<sup>1,2</sup> in combining weak and electromagnetic interactions into one theory. Finally, there are the strong interactions, which had until recently been poorly understood; but some very significant advances have been made and these are reviewed here.

The strong interaction is primarily known for its role as the powerful short-range force that binds protons and neutrons together inside atomic nuclei. In that capacity, the nuclear binding force is usually described as being due to the exchange of mesons (strongly interacting integer spin particles) such as pions between nucleons. High-energy accelerator experiments during the past several decades have shown that nuclear binding is merely one of many manifestations of the strong interaction. We now know that, in addition to the proton, neutron and light mesons, many other hadrons exist which are produced and interact with one another via the strong force. (The term hadron refers to any strongly interacting particle.) There are evidently an infinite number of hadrons which vary from the familiar stable proton to highly unstable resonances which live for much less than a billionth of a second in the laboratory. The task of a fundamental theory of the strong interaction is to account for all these diverse hadrons and to provide a dynamical description of their properties.

The current view is that the observed hadrons are not elementary particles but are bound states of truly elementary constituents called quarks, and that strong interactions between hadrons are merely epiphenomena of the more fundamental forces between quarks. Of course, the forces that bind quarks together inside hadrons must be extraordinarily strong, as experiments have not revealed an isolated free quark. Furthermore, we now believe that the strong interactions between quarks may be fully described by a quantum field theory called quantum chromodynamics (QCD). We describe here some of the major experimental and theoretical developments which gave rise to the emergence of QCD as a viable theory of the strong interaction.

### The quark model

THERE are hundreds of known hadrons (an infinite number if excitation levels are included) which exhibit widely diverse properties. This observed spectrum of hadrons is divided into two classes, mesons which have integer spin (0, 1, 2 ...) such as the pion ( $\pi$ ), kaon (K), and rho ( $\rho$ ) and baryons which have half-integer spin (1/2, 3/2 ...) such as the proton (p), neutron (n), lambda ( $\Lambda$ ), and omega ( $\Omega$ ). Examination of their specific properties indicates that mesons and baryons can be further subdivided or grouped into multiplets in which the members are all quite similar. This classification scheme is called the eightfold way<sup>3</sup>; it provides the same kind of organisation for hadrons as the Periodic Table does for chemical elements. It was the regularity of these multiplet groupings that led Gell-Mann and Zweig to conjecture that all hadrons could be built up as bound states of a few fundamental spin 1/2 constituents called quarks. Their conjecture is the basis of the quark model<sup>4-7</sup>. In this scheme, mesons are bound states of a quark (q) and antiquark ( $\bar{q}$ ), while baryons are constructed from three quarks qqq (antibaryons are made out of three antiquarks  $\bar{q}\bar{q}\bar{q}$ ). (Note that an antiparticle has the same mass as a particle but exactly opposite quantum numbers.) The mesons and baryons so constructed should have integer electric charge, even though their

constituent quarks carry fractional charge. Using these simple rules one can build all the observed hadrons out of quarks. The quark model has been very successful in predicting new hadronic states and correctly describing their properties. It is one of the cornerstones of elementary particle physics.

Five distinct species of quarks, or flavours, are known. In order of increasing mass, the quark flavours are up (u), down (d), strange (s), charm (c) and bottom (b). It is also generally believed that a sixth flavour, the top quark (t), exists at an energy somewhat higher than that now probed by accelerators. The up and down quarks are the lightest; next comes the strange quark which is about 50 times heavier than the up quark. All hadrons discovered before 1974 (the year of the  $J/\psi$  particle's discovery<sup>8,9</sup>) are built up out of these three flavours (u, d, and s); that is why they formed the basis for the eightfold-way classification scheme. Charm and bottom flavours are more recent additions to the quark model. They are respectively about 375 and 1,125 times heavier than the up quark, so their existence could only be uncovered by modern day high-energy accelerators. The top quark's mass is thought to be larger still; there may also be other even heavier flavours waiting to be discovered. All quarks carry fractional electric charge; the d, s and b have charge  $-1/3$  (in units of the proton's charge) while the u, c and t (?) have charge  $+2/3$ . These, with other quark properties, are shown in Table 1.

**Table 1** Quark flavours and their properties

Quark flavour	Symbol	Mass ratios*	Charge	Baryon no.	Spin
Up	u	1	$+2/3$	$1/3$	$1/2$
Down	d	2.5	$-1/3$	$1/3$	$1/2$
Strange	s	50	$-1/3$	$1/3$	$1/2$
Charm	c	375	$+2/3$	$1/3$	$1/2$
Bottom	b	1,125	$-1/3$	$1/3$	$1/2$
Top (?)	t	3,375 (?)	$+2/3$	$1/3$	$1/2$

\* With respect to  $m_u$ ; it is usually estimated that  $m_u \sim 4$  MeV.

Within the quark model framework, all known hadrons can be built up out of the five quark flavours u, d, s, c and b (see Fig. 1). For example, the proton is a bound state of one down and two up quarks while the neutron is made out of one up and two down quarks. Similarly, 'strange' hadrons can be made using the s quark. An example of a meson is the recently discovered spin 1  $J/\psi$  particle<sup>8,9</sup> which is now recognised as being merely one energy level of charmonium, that is a bound state of charm and anticharm ( $c + \bar{c}$ ). Similarly, an even more recent meson<sup>10</sup>, the upsilon  $T$ , is thought to be an energy level of bottomonium ( $b + \bar{b}$ ).

An assumed property of the strong interactions between quarks is that they are flavour independent and flavour conserving. This accounts then for the strong interaction conservation laws observed at the hadronic level such as isospin, strangeness, and charm conservation. Only weak interactions change the flavours of quarks. They are responsible for flavour changing decays of hadrons such as the beta decays  $n \rightarrow p^+ + e^- + \bar{\nu}_e$ , and  $\Lambda^0 \rightarrow p^+ + e^- + \bar{\nu}_e$ .

All our knowledge regarding quarks has been obtained indirectly from the properties of hadrons, as an isolated quark has never been observed. Given the outstanding success of the quark model, why have free quarks never been observed? Are quarks so tightly bound together that they cannot be dislodged from their hadronic domains? The apparent impossibility of liberating quarks has been one of the great puzzles of the quark model.

### Deep-inelastic scattering experiments

Although the quark model was very successful in classifying and accounting for the observed hadrons, there was no compelling

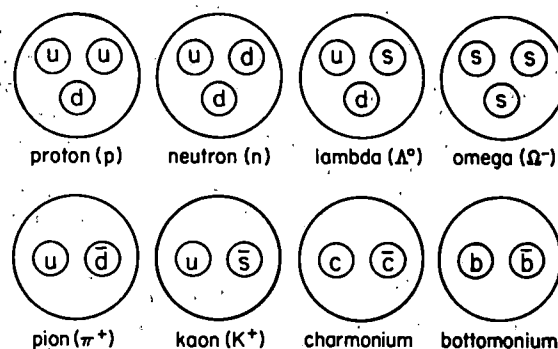

evidence that hadrons were actually built up out of quarks until the electroproduction experiments<sup>11</sup> were carried out at the Stanford Linear Accelerator Center (SLAC) in 1968. These experiments provided direct evidence that hadrons are really made up out of point-like elementary constituents.

The prototype SLAC experiment consisted of scattering a very high-energy ( $\approx 20$  GeV) beam of electrons on a proton target (see Fig. 2). (The electron (e) belongs to a class of elementary particles called leptons, which can interact electromagnetically and weakly but not strongly. Other known leptons are the muon ( $\mu$ ), tau ( $\tau$ ) and the associated neutrinos  $\nu_e$ ,  $\nu_\mu$  and  $\nu_\tau$ .) As electron-proton scattering proceeds via the electromagnetic interaction as shown by the virtual photon exchange in Fig. 2, it provides a good way of probing the proton's internal structure. If the proton's electric charge were diffused throughout the internal structure, then at very high energies the inelastic scattering cross-section would be expected to decrease very rapidly. That was not observed. Instead, the cross-section decreased slowly in a manner that suggested the proton's electric charge was concentrated in point-like constituents; these were the quarks inside the proton. When high-energy neutrino beams became available, they were also used as hadronic probes and predictions based on the quark model were again confirmed.

A surprising picture emerged from these deep-inelastic scattering experiments. Although the strong interactions of quarks seem to be very complicated at low energies, they become much simpler at high energies. Indeed, at very high energies (or equivalently at very short distances) it was found that quarks behave as though they were essentially free particles inside the hadron. This is called scaling behaviour<sup>12</sup>. Contrary to the behaviour of all other known fundamental forces, the strong interaction actually diminishes as one probes nearer the quark. An explanation of this remarkable dynamical property had to await the advent of QCD.

### Colour

In the late 1960s it became clear that the simple quark model was inadequate. In addition to flavour, quarks must carry an additional quantum number which has come to be known as colour<sup>13</sup>. Each quark flavour comes in three distinct colours; that is, there are really three times as many quarks as previously

**Fig. 1** Pictorial description of the quark content of a few well known hadrons. Inside hadrons, quarks act like free point-like particles.

described. For example, there are red, green and blue up quarks denoted by  $u_r$ ,  $u_g$ ,  $u_b$ ; they are identical in all respects (mass, charge and so on) except colour. Similarly, the other flavours also come in these same three colours ( $d_r$ ,  $d_g$ ,  $d_b$ ,  $s_r$ ,  $s_g$ ,  $s_b$ , and so on). Why was this colour degree of freedom necessary?

Colour was originally introduced as a way of reconciling quark statistics with the observed low-lying baryon spectrum. As quarks have spin  $1/2$ , they should obey Fermi statistics, that is all quantum states should be anti-symmetric (change sign) under

**Fig. 2** Deep-inelastic electron-proton scattering proceeding through the electromagnetic interaction. The final state contains many hadrons.

the interchange of two identical quarks. However, this expectation seemed to be violated by the lowest energy baryons. For example, the  $\Omega^-$  (see Fig. 2) is made up of three spin 1/2 strange quarks; so according to Fermi statistics its wave function should be antisymmetric under the interchange of any two of these quarks. But the  $\Omega^-$  has total spin 3/2 so the spin part is symmetric; and as it is the lowest energy state of three s quarks, they ought to have zero orbital angular momentum relative to one another, thereby implying that the spatial part of the wave function is also symmetric. However, the total wave function is then symmetric under quark interchange in violation of Fermi statistics. This apparent inconsistency is overcome by giving each of the quarks an additional degree of freedom, colour. Then antisymmetrising the state in the quarks' colour variables renders the  $\Omega^-$  overall antisymmetric and resolves the problem. The antisymmetrised  $\Omega^-$  state is denoted by

$$(s_r^1 s_g^2 s_b^3 - s_r^1 s_b^2 s_g^3 + s_b^1 s_r^2 s_g^3 - s_b^1 s_g^2 s_r^3 + s_g^1 s_b^2 s_r^3 - s_g^1 s_r^2 s_b^3) 6^{-1/2}$$

where the superscript labels the three distinct quark wave functions; note that it changes sign if any two quarks are interchanged (for example,  $1 \leftrightarrow 2$ ), as required. In the same way all baryons are made antisymmetric in colour; they have zero net colour. (Our choice of the standard primary colours for the quarks was arbitrary; however, it helps convey the physics, as equal admixtures of these colours yield a colourless state.) Mesons are colourless because they are made from a quark + antiquark which must have opposite colour quantum numbers.

The introduction of colour also resolved other problems, one of which was the decay rate of the neutral pion into two photons,  $\pi^0 \rightarrow 2\gamma$ . The experimentally observed rate was nine times larger than the quark model's prediction. Introducing colour increased the number of intermediate quark states and the corresponding pion decay amplitude by a factor of 3. In this way the predicted rate was increased by the necessary factor of  $9 = 3^2$ , which is further convincing evidence for three colours.

Another indication of colour's requirement came from the quantity  $R$  which is the ratio of the cross-sections for electron-positron annihilation into hadrons and muons,  $R \equiv \sigma(e^+e^- \rightarrow \text{hadrons})/\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ . Without colour, the experimental value of  $R$  was three times larger than the quark model's prediction. Introducing a factor of 3 for colour brings them into agreement. The three pieces of input, baryon statistics,  $\pi^0 \rightarrow 2\gamma$  decay rate and the value of  $R$  are the best available evidence for colour.

Why is this additional quantum number called colour? The nomenclature colour provides a convenient way of describing the fact that the observed hadrons do not carry this new quantum number, they must be colourless. It is equivalent to the mathematical statement that each quark flavour transforms as a triplet representation under an internal  $SU(3)_c$  colour symmetry; but physical hadron states are all singlets.

The quark model when appended with the  $SU(3)_c$  colour symmetry provides a good description of the observed hadronic spectrum. However, it fails to account for the dynamics of the strong interaction and leaves unanswered some obvious questions. Why do quarks inside hadrons behave as though they were free when we probe them in very high-energy experiments or

equivalently, why does the strong interaction's strength decrease in the vicinity of quarks? Why are free quarks or any other coloured hadronic states not observed in nature? QCD answers the first question and, we believe, may also answer the second one.

## Gauge theories

Quantum chromodynamics is a particular example of a general class of theories called non-abelian gauge theories. Significant developments in our understanding of these theories have occurred during the past decade which set the stage for QCD's emergence. Some of these advances will be outlined after we have briefly explained the fundamentals of gauge field theories.

The basic idea of a gauge theory is that a continuous symmetry or global invariance property of a lagrangian field theory can be made into a local invariance by introducing compensating gauge fields into the theory. This means that given a field theory which possesses a symmetry such as  $U(1)$ ,  $SU(2)$ ,  $SU(3)$  or any other Lie group, the theory can be extended to a gauge theory which has that symmetry at each point in space-time individually. The new symmetry is called a gauge symmetry because it implies that we can choose our measuring standard (gauge) (such as,  $SU(2)$  isospin basis) differently throughout space-time without changing the physics of the theory.

The most familiar example of a gauge theory is electromagnetism. In that case the symmetry group is  $U(1)$  corresponding to the freedom of changing the phase of any electrically charged field ( $\psi(x) \rightarrow e^{i\theta}\psi(x)$ ); a symmetry that follows from charge conservation. Extending this to a local  $U(1)$  gauge invariance ( $\psi(x) \rightarrow e^{i\theta(x)}\psi(x)$ ) requires the introduction of a single gauge field, the electromagnetic vector potential  $A_\mu(x)$ , which becomes the photon field in the quantum theory.

Quantum electrodynamics (QED), the quantum field theory of the electromagnetic interactions of charged particles and photons, is our most successful gauge theory. It is renormalisable, which means that all short distance (ultraviolet) divergences encountered in perturbation expansions can be absorbed into the definitions of the physical parameters (electric charge, masses, and so on); in terms of these quantities all predictions of the theory are finite. QED's predictions for precisely measured quantities such as the anomalous magnetic moments of the electron and muon and the Lamb shift in hydrogen are in perfect agreement with experiment. The incredible accuracy of QED strengthens our belief that renormalisable theories and gauge theories in particular, may also provide good descriptions of the other fundamental interactions.

The generalisation of the principle of local gauge invariance from the electromagnetic  $U(1)$  group to an arbitrary Lie group was accomplished by Yang and Mills<sup>14</sup> in 1954. Their work showed that the number of required compensating gauge fields equals the number of group generators and that in the case of

**Fig. 3** Diagrams depicting: a, electron-electron electromagnetic interaction via the exchange of a virtual photon; b, quark-quark strong interaction via the exchange of a virtual gluon; c, gluon-gluon strong interaction via the exchange of a virtual gluon. c illustrates the essential difference between QED and QCD (photons do not self-interact); this novel feature gives rise to asymptotic freedom and perhaps colour confinement as well.

non-abelian groups (SU(2), SU(3) and so on) the gauge fields interact among themselves; a novel feature with extraordinary consequences.

Non-abelian gauge theories lay dormant until two theoretical advances were made. The first was the development of a procedure for quantising non-abelian gauge theories by Faddeev and Popov<sup>15</sup>. It elevated them from classical field theories to quantum field theories in which the interacting fields could be identified with particles (quanta). The second was a formal proof of the renormalisability of non-abelian gauge theories which came from the work of 't Hooft and Lee and Zinn-Justin<sup>16,17</sup> in 1971–73. This put non-abelian gauge theories on as firm a theoretical footing as the successful QED, and made them potential candidates for describing the other fundamental interactions.

An immediate outgrowth of the work just described was renewed interest in the Weinberg–Salam model<sup>1,2</sup> of weak and electromagnetic interactions which is based on the gauge group SU(2) × U(1) (often called quantum flavourdynamics (QFD)). This theory describes and unifies all known weak and electromagnetic phenomena; it has been very successful in predicting now observed neutrino neutral current scattering cross-sections<sup>18</sup> and parity violating asymmetries in deep-inelastic polarised electron scattering<sup>19</sup>. These successes provide objective evidence that non-abelian gauge theories do describe physical phenomena.

## Asymptotic freedom

In 1973 a remarkable property of non-abelian gauge field theories was uncovered by Politzer and Gross and Wilczek<sup>20,21</sup>. They found that because of the self interactions among gauge fields, these theories exhibit the property of asymptotic freedom. That is, the strength of the interactions mediated by non-abelian gauge fields becomes vanishingly small at asymptotically high energies (or equivalently at very small distances). These theories behave almost like free field (non-interacting) theories in the asymptotic energy regime. This was precisely the property observed in the deep-inelastic scattering experiments: at high energies quarks inside hadrons behave as though they were free. Furthermore, it was shown that non-abelian gauge field theories are the only field theories which exhibit asymptotic freedom<sup>22</sup>. An obvious conclusion was that the strong interactions between quarks must be mediated by non-abelian gauge fields.

## Quantum chromodynamics emerges

The asymptotic freedom of non-abelian gauge theories fits beautifully with the quark model of hadrons and the requirement for three hidden quantum numbers called colour; from these distinct ideas and discoveries quantum chromodynamics (QCD) emerged (QCD is reviewed in ref. 23). The basic ingredients of QCD are the following: each quark flavour (u, d, s, c, b, and so on) comes in three colours (for example, red, green, and blue) which differentiate what would otherwise be three identical quarks. The three colours of quarks ( $u_r, u_g, u_b$ ) transform as a fundamental triplet of the group SU(3)<sub>c</sub> where the subscript c stands for colour. This SU(3)<sub>c</sub> symmetry is an exact symmetry of nature; it is never violated. The key new idea of QCD is that the SU(3)<sub>c</sub> symmetry must be a local gauge symmetry. This extension to a local SU(3)<sub>c</sub> gauge symmetry requires the introduction of eight vector gauge fields called coloured gluons (corresponding to the eight generators of the SU(3)<sub>c</sub> group) which transform as an SU(3)<sub>c</sub> octet. The gluons are massless spin 1 quanta which mediate the strong interaction between coloured quarks (see Fig. 3). In that way, gluons are to QCD what photons are to QED; however, an extremely important difference is that gluons carry colour and therefore interact strongly among themselves, while photons are electrically neutral and therefore cannot directly interact with one another. This distinction gives rise to asymptotic freedom in QCD (the effective coupling between

fields decreases at short distances) and perhaps other dramatic consequences as well.

The flavour quantum number of the quarks plays no role in the QCD strong interaction; all flavours of quarks interact strongly with one another in the same manner. Colour interactions are flavour blind while weak and electromagnetic interactions are colour blind.

The immediate success of QCD was that it incorporates all the earlier successes of the quark model with colour. Furthermore, this quantum field theory has all the observed strong interactions symmetries, flavour conservation, parity and time reversal invariance, and no additional unobserved symmetries. Also, if a theory of the weak and electromagnetic interactions such as the Weinberg–Salam model is appended to QCD it does not disturb these strong interactions selection rules except by small, calculable amounts, nor do the strong interactions disturb weak and electromagnetic phenomenology.

One can go beyond symmetries to real dynamics. The property of asymptotic freedom inherent to this exact non-abelian gauge theory accounts for the scaling phenomena observed in deep-inelastic electron and neutrino scattering experiments. It explains why at very high energies quarks act as though they were free particles inside hadrons. Furthermore, we now know that the scaling behaviour is not exact. There are small logarithmic deviations from exact scaling predicted by QCD and they are experimentally observed, a beautiful confirmation of the theory<sup>24</sup>.

The fact that QCD's strong interaction gauge coupling constant decreases as the energy domain probed increases (which follows from asymptotic freedom) allows one to calculate high-energy QCD effects perturbatively in this small coupling. Today an enormous effort is underway to compute QCD predictions for lepton–hadron and hadron–hadron scattering processes using perturbation theory. One observed effect that perturbative QCD accounts for nicely is the jet structure of final state hadrons produced in electron–positron annihilation ( $e^+e^- \rightarrow \text{hadrons}$ ) at high energies—the tendency of hadrons to be produced with very little transverse momentum in streams of

**Fig. 4** An unsuccessful attempt to free a quark from a bound state meson. The energy expended in pulling the quarks apart goes into creating a quark–antiquark pair out of the vacuum and thereby leads to two colourless mesons. Quarks and their colour remain confined.

narrow jet-like cones<sup>25</sup>. In principle it is possible to calculate QCD predictions perturbatively to arbitrary precision in such high energy kinematic regimes and compare with experiment; thereby rigorously testing the viability of QCD.

Another experimental-consistency check of QCD involves bound state mesons of heavy quark flavours. Heavy quark systems are a good test for QCD because the binding interaction is at short distances, so the coupling is diminished and perturbation theory becomes applicable. For example, charmonium which is a bound state of  $c$  and  $\bar{c}$  quarks has been vigorously investigated using QCD (charmonium is reviewed in ref. 26). In this way, the observed energy level splittings and various partial decay rates of charmonium have been reasonably well explained. The more recently discovered upsilon T, which is a bound state of  $b$  and  $\bar{b}$  quarks, should provide an even better system for investigating QCD effects as the coupling strength for that very massive quark system is even smaller.

Using QCD one should eventually be able to calculate hadron masses, the couplings between mesons and baryons, strong interaction cross-sections, essentially all strong interaction

phenomena. At present, the optimism surrounding QCD results from the fact that it is not contradicted where it can be checked experimentally. We can expect QCD to be subjected to more rigorous tests in the future.

There are still some outstanding problems confronting the QCD field theorist, the foremost being to prove the absolute confinement of colour. Because quarks, gluons and coloured bound states have never been observed, colour must be somehow confined (not physically observable) in QCD. It is believed at present that as one tries to break a colourless hadron apart into its coloured constituents, the potential energy grows linearly until there is enough energy to create new quark-antiquark pairs and gluons out of the vacuum. In this way the hadron can divide into several colourless hadrons, so that quarks, gluons and their colour remain confined (see Fig. 4).

One way that this scenario might be realised in QCD is through 'infrared slavery'—the opposite of asymptotic freedom. Infrared slavery means that the self-interaction of non-abelian gauge fields causes the inter-quark and -gluon couplings to become very large at large distances (perhaps infinite). This accounts for strong quark binding and might, hopefully, imply colour confinement.

**Fig. 5** *a*, Electric field lines between positive and negative electric charges. *b*, Sketch of the anticipated colour field lines between a quark and antiquark. The lines in (*a*) give rise to a Coulombic potential  $\sim 1/r$ , and those in (*b*) give rise to a linear confining potential  $\sim r$ .

Another possibility is that the colour gluon fields may form a flux tube or string between colour sources. If the coloured flux in the tube is conserved it is easy to show that the potential energy between sources rises linearly with the separation, implying confinement of colour (see Fig. 5).

Another idea is that the vacuum state surrounding a hadron is a very complicated strong coupling regime. The hadron is a little bag or bubble in this vacuum describing a two-phase system. The quarks and gluons inside are in relatively free motion. Only if the quarks or gluons try to escape from the bag do they experience strong confining forces. This is essentially the phenomenologic-

ally successful MIT bag model (see the review in ref. 27). The problem is to show that such a bag picture of hadrons actually follows from QCD.

There are other problems besides that of the colour confinement. The pion ( $\pi$ ) seems experimentally to be a collective excitation of quarks rather than an atomic bound state. This property of pions can be understood as the spontaneous breaking of the right-left symmetry of the quarks (chiral symmetry). The problem is to show that in QCD chiral symmetry is actually spontaneously broken.

A new class of gauge field configurations, instantons<sup>28</sup>, have recently been discovered in the classical non-abelian gauge theories and they may provide a better understanding of the quantum theory (for example, QCD). In the quantum theory, instantons imply that tunnelling takes place between topologically distinct vacuum states. There are already suggestions that instantons may be responsible for breaking chiral symmetry in QCD thus elucidating the pion's properties. Instantons may also lead to a two-phase structure in QCD—strong and weak coupling—that could give rise to a bag picture of confinement<sup>29</sup>. Many theorists are trying to solve these problems and elucidate QCD's properties.

## Outlook

QCD and QED (Weinberg-Salam model) are both non-abelian gauge theories. Together they describe strong, weak and electromagnetic interactions. The next natural step is to embed these two distinct theories in a larger compact covering Lie group, for example, SU(5) (ref. 30), and thereby construct a grand unified theory of strong, weak and electromagnetic interactions. Such a theory has only one gauge coupling constant, so all three interaction strengths are equal at very short distances (true unification); however, this unification only becomes apparent at ultra-high energies  $\sim 10^{16}$  GeV. In these types of models leptons and quarks belong to the same group representations. So leptons, such as the electron, are very much like quarks; but they are not strongly interacting and are liberated because they do not carry colour. A novel prediction of many such grand unified models is that baryon number is not absolutely conserved; so the proton may actually decay! (Its half life is  $\tau_p \geq 10^{30}$  yr.) This predicted instability is being looked for experimentally. Ultimately, one wants to bring gravity into this unification scheme; however, in spite of much effort a renormalisable quantum theory of gravity is not known to exist.

For decades high energy theorists have sought a fundamental theory of the strong interaction: many are now convinced that QCD is the answer. It can be explicitly written down as a renormalisable quantum field theory; the problem has become to solve QCD and make further experimental contact. The endurance of the concept of a continuum quantum field theory as a way of understanding physics at  $10^{-13}$  cm and smaller is especially remarkable.

The shift in emphasis from searching for the theory of the strong force to solving it may revitalise the symbiosis of mathematics and physics in the coming decades. Strong interaction physics could become like atomic physics after the Schrödinger equation.

## Re-appraisal of lithostratigraphy of Makapansgat Limeworks hominid site

T. C. Partridge

Palaeo-anthropology Research Group, Department of Anatomy, University of the Witwatersrand, Johannesburg, South Africa

*A new lithostratigraphic classification is proposed for the Makapansgat Limeworks hominid site. The Makapansgat Formation is defined in terms of constituent members and beds. The new terminology is correlated with that used previously and hominid finds are linked to the newly defined lithostratigraphic units.*

THE stratigraphy of the hominid site at Makapansgat Limeworks, where *Australopithecus africanus* was discovered in association with a rich fauna in 1947, has been described in several publications. Between 1947 and 1957 several broad descriptive classifications were proposed<sup>1-5</sup>. The first detailed stratigraphic and sedimentological analysis appeared in 1958 (ref. 6) and has provided the standard lithostratigraphic subdivision of the deposit until recently. The re-appraisal of the hominid deposit reported here was necessary because earlier studies omitted several important subdivisions within major stratigraphic units. In this re-appraisal I call the hominid-bearing deposit the Makapansgat Formation.

### Location and origin

The Makapansgat Formation comprises a large cave filling at the Makapansgat Limeworks (24°08' S, 29°11' E). It is exposed both at surface and abandoned lime quarries at elevations of 1,440–1,475 m. At the surface the maximum dimensions of the deposit are approximately 200 × 115 m, increasing slightly with depth. The outcrop area is associated with a pronounced bench on the steep southeastern slopes of the Dorps river valley.

The deposition and subsequent modifications of the sedimentary sequence were very similar to those at the Sterkfontein hominid site, described previously<sup>7</sup>. A similar origin, conforming to the model of karst development proposed for the Transvaal<sup>8</sup>, is postulated for the original solutional receptacle at Makapansgat. The Malmani dolomite here dips south at a low inclination; together with joints and small faults, this small dip caused preferential solution and influenced the form of the original cavern<sup>8</sup>. Considerable modifications resulted from later roof collapses. The present water table is controlled by the episodic Dorps river, and is usually below the level of the valley floor, ~15 m below the base of the formation.

Small remnants of the original dolomite roof are preserved over the deposit, but much of its surface has been bevelled by erosion of the hillside. Reconstructions based on the positions and inclinations of the roof segments suggest that the maximum elevation of the original roof reached ~20 m above the present surface. Hence the absolute thickness of the deposit may have approached 50 m in places; less than 60% of this is preserved.

As with the Sterkfontein Formation<sup>7</sup>, the stratigraphic relationships are complex, and the schematic column in Fig. 1 merely reflects the relative average thicknesses of the various units in accessible areas of the deposit.

### Lithostratigraphy

Samples were prepared in the same way as those from Sterkfontein<sup>7</sup>. They were recovered in vertical succession from four areas at an average vertical separation of <2 m; supplementary samples were recovered from other localities to monitor lateral variations in sedimentary facies.

The very coarse (>2 mm) fraction of all units was examined visually. In the lowest members (1–3) it is chiefly bone and broken speleothems, although occasional pebbles and cobbles of dolomite, chert, quartzite and shale occur in Member 3. In Members 2 and 3 much of the bone is stained with pyrolusite, and many of the broken speleothems show post-depositional weathering. In Member 4 the very coarse fraction is predominantly angular cobbles and boulders of chert and dolomite; many individual fragments are fresh on one or two faces with thin weathering skins on others, indicating that they accumulated through intracavernous collapses of the roof and projecting ledges. The finer component includes subrounded chert pebbles and cobbles whose deeper and more uniform weathering is compatible with an extracavernous colluvial source. Occasional weathered quartzite pebbles and cobbles are present. Quartzite and shale horizons are interbedded in the Malmani dolomite on the upper valley slopes to the south-east of the site.

The very coarse fraction of Member 5 consists overwhelmingly of deeply weathered subangular to subrounded dolomite pebbles and cobbles with few chert and quartzite pieces.

**Member 1** is exposed over most of the cave above the irregular dolomite floor, or overlying large collapsed roof-blocks. It consists of 0.5–15.0 m of white banded reddish-brown (5 YR 5/4), recrystallised meso- and macro-crystalline calcite, locally contaminated with silty loam (clayey, sand-silt). It is thickest in two major stalagmitic bosses, one aligned north-south through the Entrance Quarry (see Fig. 2), the other along the south-east wall of the cave. Concentrations of bone, sometimes as articulated partial skeletons, are present in the distal areas; occasional moderately inclined centimetre beds and cross-beds are visible. The evidence suggests that extracavernous components entered through a relatively small opening near the northern end of the cave. CaCO<sub>3</sub> generally exceeds 80% and average  $\phi$  mean is 6.0 ( $\phi$  is the negative logarithm to the base 2 of the particle diameter (mm)). Sediments are poorly sorted<sup>9</sup> and leptokurtic or highly leptokurtic with pronounced positive skewness. Crystalline minerals (in decreasing order of abundance) are quartz, kaolinite and sericite. Typical particulate roundness and sphericity are 0.3 and 0.5 respectively, and conform with those of present external colluvial soils. As in most succeeding units, quartz particles predominate; chert and dolomite grains are infrequent. Pyrolusite and ferric skins are present on a few particles. Contact is abrupt and wavy.

These features suggest episodic subaqueous deposition of the clastic material with illuvial enrichment in fines. Cross-stratification indicates locally channelled flow during episodic

storms, with relatively high water velocities occurring away from high points in the floor near the centre and entrance of the cave. These could have swept carcasses from the entrance into distal recesses.

**Member 2** is exposed to the west and south-west of both the Entrance and the Exit Quarries, where sedimentation occurred penecontemporaneously in two separate depositories separated by a high area in the surface of Member 1. It consists of 2.0–10.0 m of yellowish-red (5 YR 5/8), and, less frequently light to medium red (2.5 YR 6/6 and 4/8) or light reddish-brown (5 YR 6/4), mostly centimetre-bedded and cross-bedded, silty loam (clayey sand-silt), containing frequent broken speleothems, recrystallised calcite lenticles, and with local concentrations of bone, including some articulated partial skeletons in distal areas. Pebble-sized rolled calcite and bone fragments have sometimes been retained in irregularities in the inclined surface of Member 1 near the position of the original cave opening, and marked lateral changes of facies are evident. Occasional lenses of spongy collophanite and oolitic concretions occur near the top of the member, which has a very uniform upper surface at approximately 1,458 m.  $\text{CaCO}_3$  averages 56% and average  $\phi$  mean is 5.3. Sediments are poorly to very poorly sorted and mesokurtic to leptokurtic and samples have a wide range of skewness from negative to positive. Crystalline minerals are quartz, sericite and haematite. Typical roundness and sphericity are 0.1 and 0.5, indicating higher angularity than is characteristic of the present external colluvial soils. A few particles have pyrolusite and ferric skins. Contact is eroded, slightly wavy and abrupt, and truncates the uppermost cross-beds. The sedimentology indicates deposition of this member beneath the fluctuating surface of a water table which reached about 1,458 m, with local flushing of some fines into more distant depositories. Fairly widespread cross-beds with rolled calcite pebbles and bones in the proximal facies indicate channelled flow with relatively high water velocities down the irregular, sloping surface of Member 1. As in Member 1, these flows could have carried carcasses into recesses. The collophanite lenses indicate significant bat populations towards the end of this deposition.

**Member 3** is exposed at the southern end of the cave to the east and west of the Cone area, where it consists of 0.5–2.0 m of abundant bone fragments (some semi-articulated) in a matrix of very pale brown (10 YR 8/3 and 8/4) and brownish-yellow (10 YR 6/6), sometimes blotched reddish-brown (2.5 YR 5/4) and black, sandy to silty loam (slightly clayey silty sand), containing extensive calcite intergrowths, numerous broken speleothems, occasional pebbles of dolomite, chert, quartzite and shale, carrion fly pupae, a few coprolites and frequent pockets of collophanite. Most of the deposition occurred in the stalactite fringe immediately below the dolomite cave roof, and crude stratification is present within the bone fragments between stalactite clusters. Flow diversion around the latter has increased bed-shear and created extensive bone lags showing variable particle orientations.  $\text{CaCO}_3$  averages 67% and average  $\phi$  mean is 4.6. Sediment samples show much variation, but are generally very poorly sorted and platykurtic to leptokurtic with a wide range of skewness from negative to positive. Crystalline minerals are quartz, fluorapatite, sericite and chlorite. Typical roundness and sphericity are 0.3 and 0.5, and a very few particles have pyrolusite skins. Comminuted bone and chert particles are relatively abundant. Where Member 3 is present vertically below Member 4, for example east of the Cone, it is overlain by some 0.5 m of laminated, recrystallised meso- and macro-crystalline calcite. Contact between Member 3 and calcite is slightly wavy and abrupt.

The characteristics of Member 3, which has produced the majority of the fauna and hominid remains, are consistent with rapid alternations in depositional conditions with the occurrence of several short, high-energy cycles, which coincide with large fluctuations in concentration of the isotopes  $^{13}\text{C}$  and  $^{18}\text{O}$  in the calcite fraction of the matrix<sup>10</sup>. Quieter episodes apparently alternated with vigorous flows which carried bone fragments and

Fig. 1 Stratigraphic column of the Makapansgat Formation.

dismembered carcasses towards the back of the cave and winnowed some finer particles. Between sheetfloods decomposing carcasses attracted carrion flies. The restricted roof height and distance from the cave opening argue against any lengthy occupation of this area by predators or scavengers; such creatures probably concentrated their activities near the cave mouth. Their coprolites could have been incorporated in the deposit during episodes of quieter flow.

**Member 4** consists of beds A and B. Bed A is exposed chiefly in the Entrance Quarry and is composed of 0.5–2.0 m of pink (5 YR 7/4) or light red (2.5 YR 6/6), locally decimetre-bedded, silty loam (clayey silty sand), containing numerous large oolitic concretions, occasional recrystallised calcite lentils and infrequent angular chert and dolomite pebbles and cobbles; some bones and carrion fly pupae are present. Towards the northern end of the Exit Quarry it takes the form of a dense accumulation of rodent bones in a similar fine matrix, which indicates the presence of local owl roost.  $\text{CaCO}_3$  averages 92% and the average  $\phi$  mean is 4.65. Sediments are very poorly sorted and platykurtic to leptokurtic with negative skewness. Crystalline minerals are quartz and sericite. Typical roundness and sphericity are 0.3 and 0.5. Pyrolusite skins are rare. Contact is gradational. These features argue for the deposition and redistribution of sediments in an environment of shallow, localised pools accompanied by winnowing of some fines.

Bed B is present throughout the central part of the cave; it is the most extensive stratigraphic unit, and lime-workings have almost everywhere isolated it from the cave walls. Over substantial areas where the cave floor is high, it overlies either Member 1 or Member 2. It is composed of 2.0–15.0 m of light reddish-brown (5 YR 6/4), less frequently pink (5 YR 7/3), reddish-yellow (5 YR 6/6) or red (2.5 YR 5/8), loam (clayey silty sand), containing abundant broken speleothems, chert and dolomite pebbles, cobbles and boulders, a few quartzite pebbles, occasional bone fragments and recrystallised calcite lentils and void linings. The frequency of chert and dolomite fragments increases upwards, and these display crude stratification parallel to the flanks of a debris cone with its apex near the northern end of the deposit. Highest bone concentrations occur along the cone periphery near the cave walls, suggesting that bones were redistributed toward its margins.  $\text{CaCO}_3$  averages 86% and average  $\phi$  mean is 4.95. Sediments are extremely poorly sorted and samples are mostly mesokurtic, with a wide range from platykurtic to leptokurtic. There is a similar range in skewness from negative to positive, with the latter predominating. Crystalline minerals are quartz, sericite and weakly crystallised montmorillonite. Typical roundness and sphericity are 0.3 and 0.7, indicating greater rounding than is characteristic of present external colluvial soils. Pyrolusite and ferric skins are rare. Contact is eroded and disconformable and is locally complicated by subsidence movements.

The characteristics of this bed are consistent with redistribution of gravelly colluvium and some aeolian material, in admixture with frequent roof collapse debris, down the flanks of a cone of gravitative accretion under the influence of episodic sheetfloods entering through an enlarged cave opening. Higher energy conditions are evident towards the middle of this unit.

**Member 5** consists of beds A–E. All are exposed in conformable sequence around the margins of the Cone. The uppermost unit (bed E) also occurs in isolated pockets to the west of the Entrance Quarry, in the eroded surface of Member 4, and in Horse Mandible Cave. In the Cone area deformation and displacement of an underlying calcite horizon indicates that Member 5 accumulated in a large depression formed by subsidence of underlying deposits into lower cavities; it is likely that similar movements preceded sedimentation in Horse Mandible Cave. Beds A, B and D are gravelly and are often lenticular in form, grading laterally into sandy facies. The latter often preserve carrion fly pupae.

Bed A consists of 1.0–2.0 m of yellowish-red (5 YR 5/6), silty loam or loam (clayey silty sand), containing abundant subangular or subrounded pebbles and cobbles of partially weathered

dolomite, occasional chert and quartzite pebbles, and a few badly damaged bone fragments. Good sub-horizontal stratification is present in the very coarse fraction. A single sample had a  $\text{CaCO}_3$  content of 69% and a  $\phi$  mean of 5.1. The sediments are extremely poorly sorted and mesokurtic with small positive skewness. Crystalline minerals are quartz, sericite, haematite and kaolinite. Typical roundness and sphericity are 0.3 and 0.7, and pyrolusite skins are uncommon. Contact is sloping and fairly abrupt.

Bed B includes 3.0–6.0 m of pink (5 YR 7/4) becoming red (2.5 YR 5/6) where decalcified, unbedded loamy sand (slightly silty sand), containing abundant subangular to subrounded pebbles, cobbles and boulders of partially weathered dolomite, a few chert and quartzite pebbles, and occasional badly damaged bone fragments.  $\text{CaCO}_3$  is about 73% where calcified, but falls to about 50% where calcite cement has been removed by solution; average  $\phi$  mean is 2.1. Sediments are very poorly sorted and mesokurtic with pronounced positive skewness. Crystalline minerals are quartz, feldspar, sericite and kaolinite. Typical roundness and sphericity are 0.3 and 0.5 and pyrolusite and ferric skins are rare. Contact is even and abrupt.

Bed C consists of 2.0–10.0 m of red (2.5 YR 5/8), decimetre-bedded loamy sand (slightly silty sand), with a negligible very coarse fraction. Bones are few and badly damaged. A single sample had a  $\text{CaCO}_3$  content of 39% and a  $\phi$  mean of 2.6. Sediments are very poorly sorted and mesokurtic with pronounced positive skewness. Crystalline minerals are quartz, sericite and haematite. Typical roundness and sphericity are 0.3 and 0.5 and pyrolusite skins are rare; ferric skins are slightly more abundant. Contact is even and abrupt.

Bed D comprises a distinct near-horizontal gravel band which lenses out and bifurcates locally. It consists of up to 1.0 m of yellowish-red (5 YR 5/6), silty loam (slightly clayey silty sand), containing abundant subangular to subrounded pebbles and cobbles of partially weathered dolomite, occasional chert and quartzite pebbles, and a few badly damaged bone fragments. The very coarse elements show good sub-horizontal stratification. A single sample had a  $\text{CaCO}_3$  content of 56% and a  $\phi$  mean of 4.05. The sediments are very poorly sorted and platykurtic with negative skewness. Crystalline minerals are quartz, sericite and haematite. Roundness and sphericity and the presence of skins are akin to those in Bed C. Contact is even and abrupt.

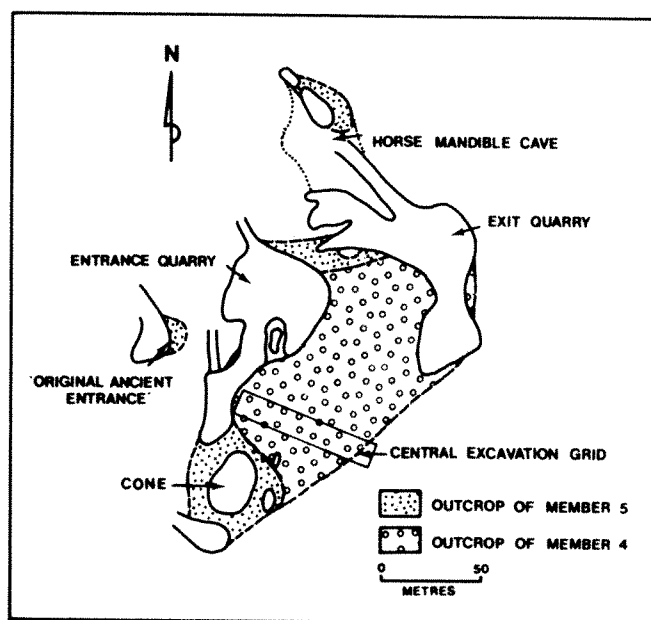

Fig. 2 Locality plan showing the surface extent of the Makapansgat Formation and the positions of localities mentioned in the text.

**Table 1** Comparative terminology of Makapansgat Formation

Previous terminology	Present terminology	Hominid remains
(Brain <sup>6</sup> ) Phase II (red sandy and gravelly) breccia	Member 5	—
Upper Phase I (pink stoney) breccia	Bed A and lower bed B of Member 5 and Member 4	MLD 37/38 from bed B of Member 4
Lower Phase I Grey bone-rich breccia	Member 3	Remainder of specimens of <i>A. africanus</i>
Red calcified muds	Member 2	—
Contaminated travertine	Member 1	—

Bed E consists of 1.0–5.0 m of red (2.5 YR 4/6 and 5/6), and less frequently yellowish-red (5 YR 5/8) and reddish-brown (5 YR 5/4), decimetre-bedded sandy loam (slightly clayey silty sand), with a small very coarse fraction of the type present in the remaining beds, and occasional recrystallised calcite lenticles. CaCO<sub>3</sub> averages 65% and average  $\phi$  mean is 3.8. Sediments are very poorly sorted and samples show a wide range of kurtosis from platykurtic to leptokurtic, but are almost all negatively skewed. Crystalline minerals are quartz, feldspar and sericite. Typical roundness and sphericity are 0.3 and 0.7, indicating greater rounding than is characteristic of the present external colluvium. Pyrolusite and ferric skins are somewhat more numerous than in previous beds.

Viewed as a sequence, the five beds of Member 5 suggest deposition by rapid episodic flushing of unconsolidated gravelly soil from the hillside into depressions containing impermanent pools. The presence of a large proportion of subrounded, weathered dolomite fragments suggests that this gravelly material may have been an alluvial terrace or a mudflow deposit, which had undergone a degree of post-depositional weathering before being washed into the cave. However, the fine matrix certainly includes a large colluvial component. The cave openings seem to have been greatly enlarged after deposition of Bed A. Illuviation of fines from upper to lower beds is evident, suggesting relatively slow and inefficient calcification after cessation of sedimentation. There is distinct evidence for an energy increase in Beds B and C, but damage to bone fragments in conjunction with the presence of stratified gravel lenses suggests the existence of high energy levels during deposition of most of the member. The morphology of Bed B, with its conspicuous lack of stratification indicates a rapid mass movement following renewed subsidence during its accumulation.

### Extracavernous source materials

Comparative analyses of deposits from the vicinity indicate that the –2 mm fraction of the various units was derived mostly from extracavernous colluvial sources except in Member 5, where a significant alluvial (?) component is evident, especially in the very coarse fraction. The contribution of the insoluble residue produced by intracavernous corrosion is chiefly restricted to a few highly angular chert particles.

The present colluvium has relatively uniform properties; it is a pebbly, skeletal soil containing abundant, partially weathered, chert pebbles and cobbles. The characteristics of the Makapansgat Formation can be explained in terms of the reworking of this material. It is a dark reddish-brown (5 YR 3/3 and 3/4) sandy loam (slightly clayey silty sand) containing abundant weathered chert pebbles and cobbles, and seldom exceeding 50 cm thick. The  $\phi$  mean averages 2.8. The material is very poorly sorted and is mesokurtic and samples show a wide range of skewness, both negative and positive. Crystalline minerals are quartz, sericite and kaolinite. Typical roundness

and sphericity are 0.3 and 0.5 and many particles have pyrolusite skins.

In Member 5, while a large colluvial component seems to be present in the fine matrix, the very coarse fraction has many of the characteristics of an alluvial or mudflow deposit.

Sedimentary facies of the various units of the Makapansgat Formation can be explained through the reworking of extracavernous colluvium by a limited suite of transportational and depositional processes. The colluvium contributing to Member 1 has been enriched in fines, while that of Member 2 shows that, although fines have increased overall, as expected with subaqueous deposition at a distance from the cave entrance, some winnowing has taken place, especially in proximal facies produced by rapid channelled flow. Winnowing of fines is even more evident in Member 3, where it seems to have occurred during several cycles of flushing. The source material for Bed A of Member 4 seems to have been subjected to similar, but probably less intense flushing. In Bed B of Member 4 enrichment in fines is widely evident, possibly due to an aeolian component, although local winnowing can be discerned away from the walls of the depository. Some enrichment in fines, evidenced by pronounced positive skewness, has occurred in beds A–C of Member 5, probably due to post-depositional illuviation from the upper beds before calcification of the deposit.

In general, fine sedimentary fractions are more abundant in lower members, due to a greater degree of illuviation with increasing distance from the cave opening. Removal of fines can be attributed to flushing and eluvial effects as sheetfloods spilled into the cave opening(s) and were channelled downwards into more distant caverns.

Extensive hiatuses in clastic deposition within the cave, sometimes associated with calcite accretion, indicate cycles with reduced influx of extra-cavernous sediments. In some instances such episodes were marked by intra-cavernous scouring and the production of erosional unconformities.

### Solution cavities and discrimination between members

Solution cavities, often exceeding 5 m in depth, were formed in the eroded surface of the Makapansgat Formation chiefly in Bed B of Member 4. These contain residual material, produced by decalcification and *in situ* weathering of the surrounding sediments; this is overlain by recent colluvium with a clear transition. The residual material is occasionally bone-bearing, and is similar in its properties to that occurring in solution cavities in the Sterkfontein Formation<sup>7</sup>.

Sedimentological analysis of samples from the various lithostratigraphic units of the Makapansgat Formation reveals that successive members are distinctive in terms of the standard deviation of at least one of the associated quartile and moment measures or of the sedimentological characteristics of their very coarse fractions.

### Comparison with Sterkfontein and Swartkrans Formations

The stratigraphies of the Sterkfontein and Swartkrans hominid sites, ~250 km to the south-west, have been re-appraised recently<sup>7,11,12</sup> and the Sterkfontein and Swartkrans Formations have been defined. Comparison of these formations with the Makapansgat Formation shows that, although similarities exist, each is distinctive in terms of the sedimentology of specific constituent members and its particular sequence of erosional and depositional events. The fauna thus far recovered from Members 1–4 of the Makapansgat Formation has no equivalent at Swartkrans,<sup>13</sup> but is considered broadly similar to that from the Sterkfontein Type Site (Member 4)<sup>13–14</sup>, although no results have as yet been published which distinguish comprehensively between the faunas present in the various subdivisions of the Makapansgat Formation; these clearly span a substantial period. However, Wells<sup>16</sup> believes that important differences

between the Sterkfontein and Makapansgat faunas suggest that that from Makapansgat (mostly the lower members) is the older. Palaeomagnetic evidence from the Makapansgat Formation<sup>17,18</sup> permits the fairly definite conclusion that Member 1 predates 3.32 Myr, while Member 3 predates 2.90 Myr. Faunal age estimates for the Sterkfontein Type Site fall in the range 2 to 3 Myr. More precise correlations between the faunas of the two sites must await further studies of the respective assemblages.

### Correlation with previous terminology and hominid finds

In Table 1 the published stratigraphic terminology of previous workers at Makapansgat Limeworks is cross-referenced to the terminology used here. The table also gives an indication of the known or likely provenance of the hominid remains.

Excavations undertaken so far have sampled very small volumes of the *in situ* deposits, the remaining faunal and hominid material having been extracted from material discarded on dumps during lime quarrying operations. The vast majority of finds can be correlated with the rich bone accumulation of Member 3.

I have not considered biostratigraphic aspects of the Makapansgat formation here; these, together with the environmental implications of the data, will be discussed elsewhere.

I thank the University of the Witwatersrand, especially the Bernard Price Institute for Palaeontological Research, for access to the site, Professor P. V. Tobias and A. R. Hughes for comment and encouragement, and Drs C. K. Brain, E. S. Vrba and A. J. Tankard for useful discussion.

# A late Proterozoic ophiolite complex at Jabal Ess in northern Saudi Arabia

M. Shanti & M. J. Roobol

Faculty of Earth Sciences, King Abdulaziz University, Jeddah, Saudi Arabia

*A folded and lightly-metamorphosed allochthonous thrust slice, representing a complete ophiolite succession (Penrose definition), has been mapped in the late Proterozoic shield of Saudi Arabia. This occurrence supports the suggestion that plate-tectonic motions operated during the late Proterozoic.*

The late Proterozoic stratigraphy of the Arabian Shield is fundamental to the question of whether plate-tectonic motions operated in the Precambrian<sup>1,2</sup>. This vast area of igneous rocks (1,200 km N–S and 600 km E–W) comprises about two-thirds plutonic rocks and one-third lightly-metamorphosed lava flows and volcanoclastics. High-grade metamorphic areas are minor. The shield is characterised by radiometric ages from 1,190 to 530 Myr<sup>3–5</sup>. Within it there are many serpentinised bodies and belts<sup>6</sup>; some extend discontinuously for up to 700 km. The term 'ophiolite' has long been used in the description of these complexes<sup>7,8</sup> and more recently some have been more convincingly identified as incomplete ophiolite complexes<sup>9,10</sup> in the sense of the Penrose field meeting of 1974<sup>11,12</sup>. More recently the serpentine belts have been postulated to be ophiolitic sutures<sup>8,9,13,14</sup>, formed by the closure of oceanic basins. These interpretations, amongst others, have led to a proposed mechanism of evolution of the Arabian Shield by the plate-tectonic opening and closing of sialic crust<sup>15</sup> or by the accretion of island arcs<sup>16</sup>. However, a complete ophiolite succession in the sense of the Penrose definition has never been described in the Arabian Shield, although it has been sought for some years. The most detailed study at Jabal al Wask<sup>9</sup> reported serpentinised ultramafic rocks (dunite, harzburgite, wehrlite, pyroxenite and chromitite), cumulate and high level gabbros and a metabasalt-keratophyre volcanic association. Recently an alternative

explanation for some of the serpentine belts both in Saudi Arabia and Egypt has been proposed<sup>17,18</sup>—that they are serpentinised komatiitic sills. We describe here a complete ophiolite succession from a new locality in the northern shield of Saudi Arabia (Fig. 1).

## Stratigraphy of the Jabal Ess area

The three components of the mapped area are (1) a meta-sedimentary sequence; this is concordantly overlain by (2) the Jabal Ess ophiolite complex, which is in turn overlain and fault-separated from (3) an upper meta-volcanic sequence.

The stratigraphic succession of the area from bottom to top is: (1) **The meta-sedimentary sequence:** south of the ophiolite complex is a sequence of lightly-metamorphosed, pale-green sediments. Strata vary from 1 to 30 m thick, with most around 2 m. The common rock type is a green shale, often with well-developed pencil cleavage. Less common are pebbly shales and conglomerates. Pebbles are well rounded and up to 20 cm in diameter. They are usually stretched, but have mainly lost their original identity due to chloritisation, with only chert and gabbro clasts recognisable. Several lenses of *mélange* up to 10 m thick and composed of gabbro and serpentine, are concordantly contained within the meta-sedimentary sequence.

(2) **The Jabal Ess ophiolite complex:** this complex has a minimum exposed thickness of about 3 km, but is very condensed by folding and faulting (Fig. 1b). It has been divided into nine components, which from bottom to top are: (i) *The mélange zone*, which is up to 250 m thick, and discontinuously present along the southern limit of the ophiolite complex. The *mélange* consists of blocks of leucocratic meta-gabbro (containing meta-dolerite dykes), melanocratic meta-gabbro, pillow lava and dolerite in a sheared serpentine host. Some blocks are up to 30 m in diameter. A lens of sheared serpentine from 2 to 10 m

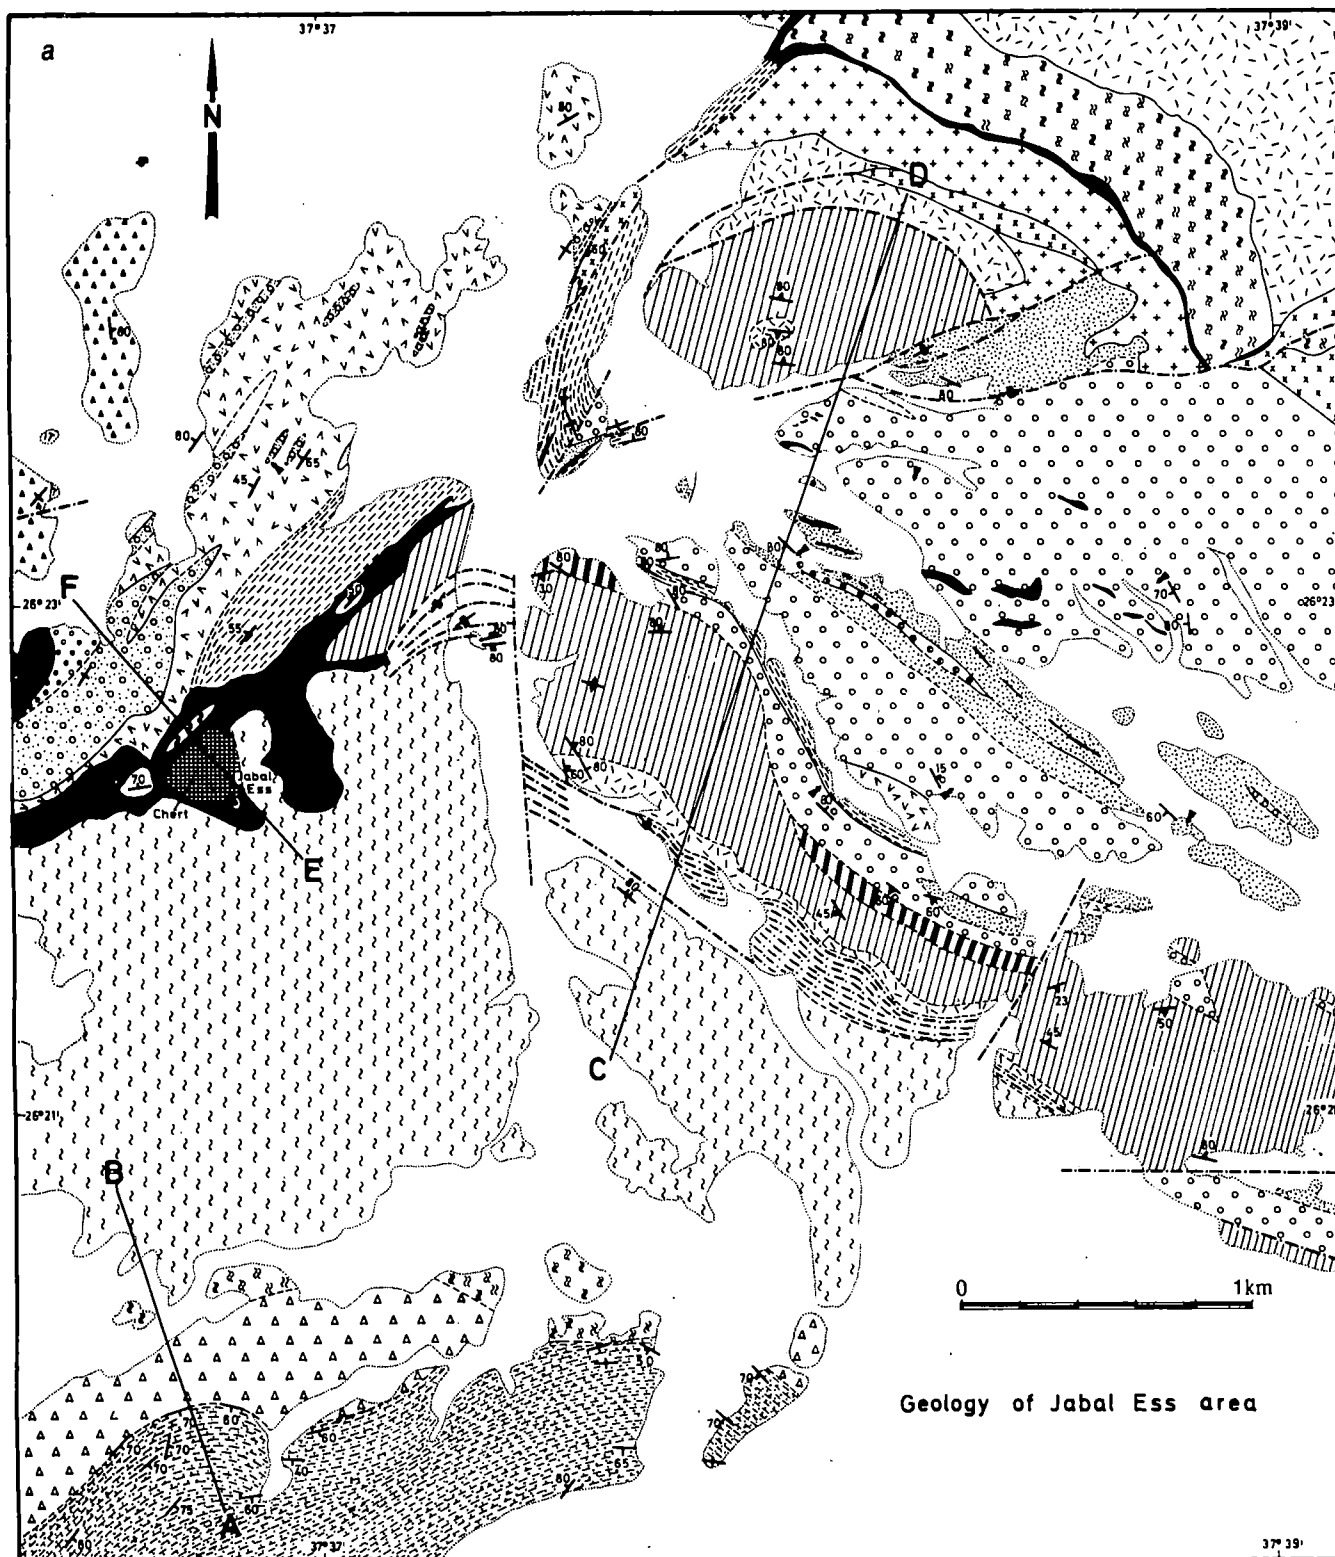

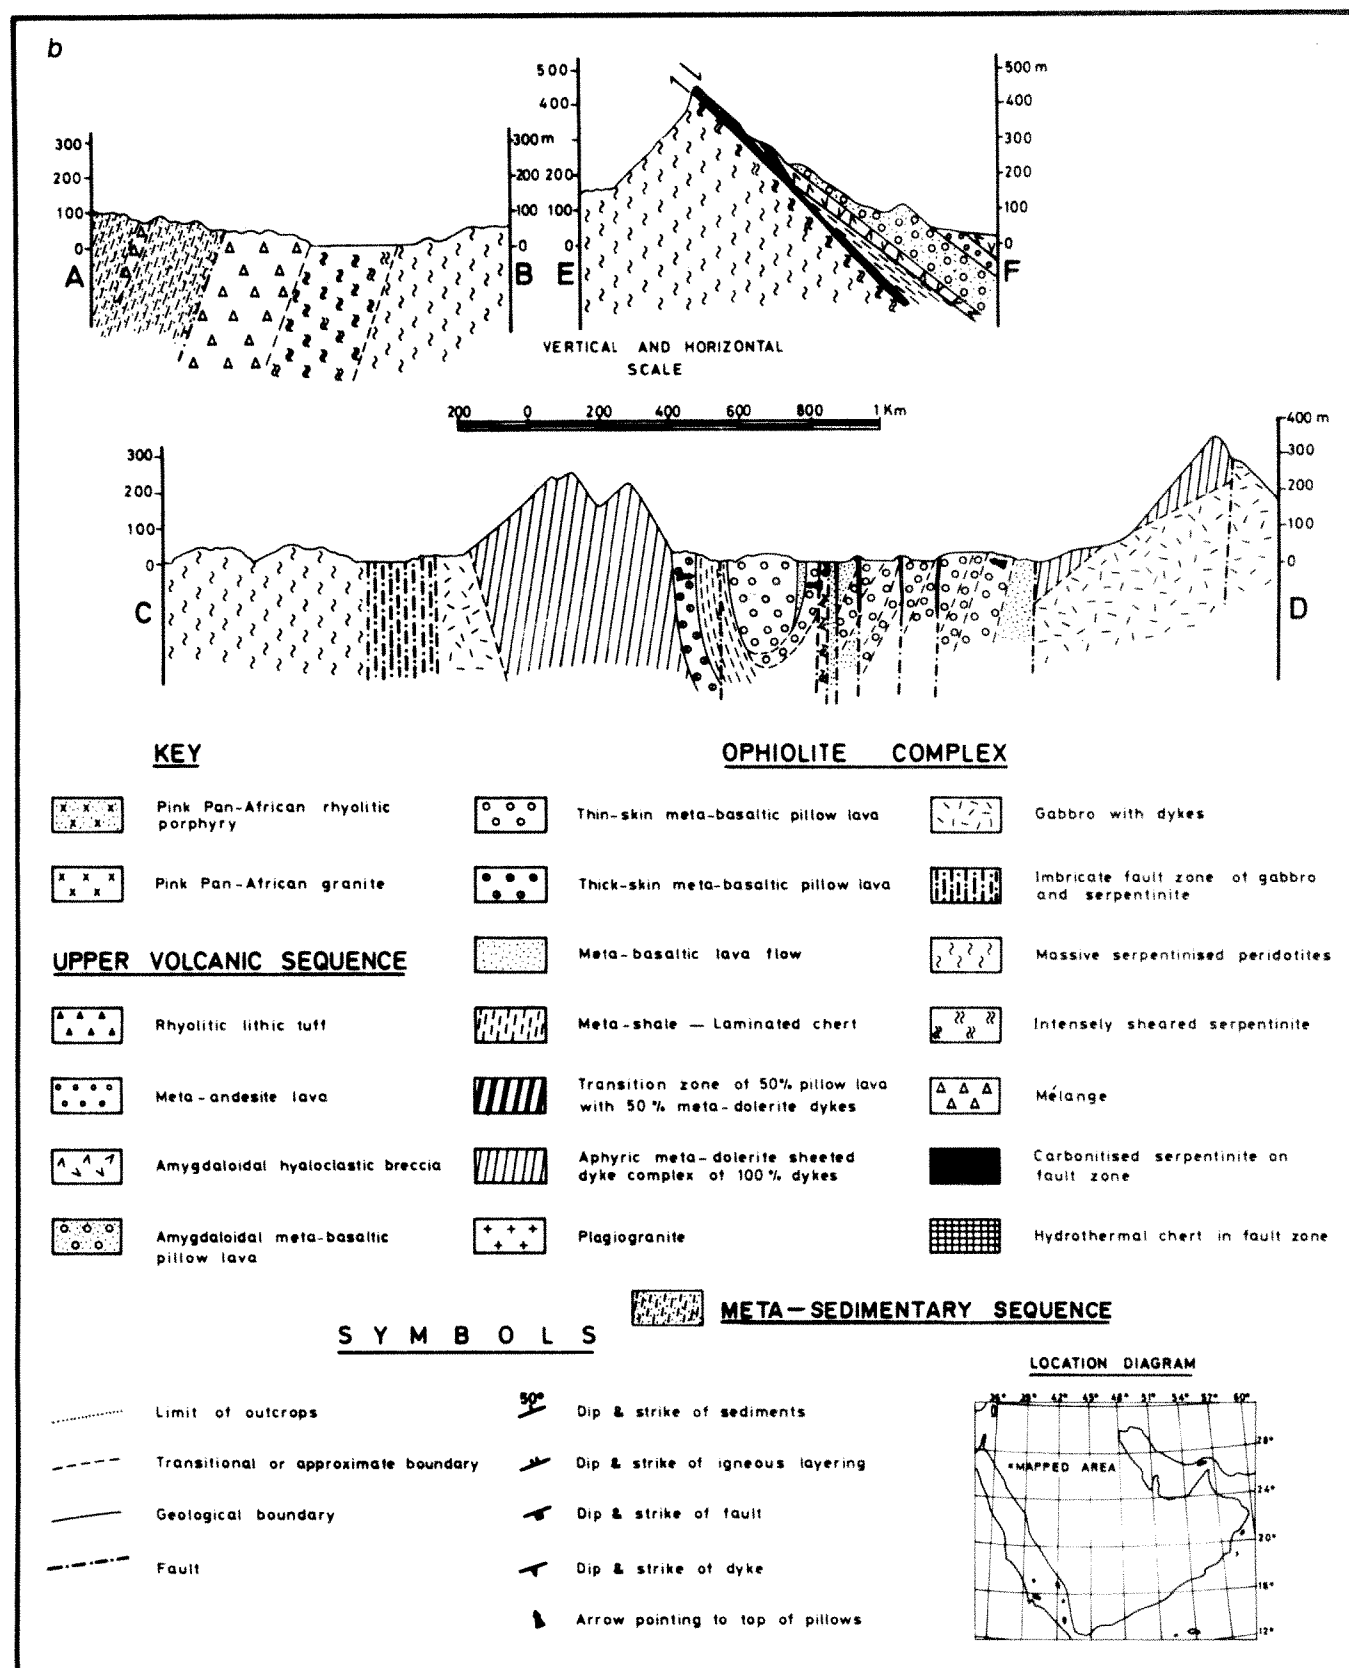

Fig. 1 a, Geological map of the Jabal Ess area, Saudi Arabia; b, (overleaf) cross-sections of the area are shown in a.

wide, which contains blocks of melanocratic meta-gabbro, occurs in direct contact with the meta-sedimentary sequence. Stratification of the meta-sediments and the contact with the mélangé are concordant but folded and overturned in the mapped area. (ii) *Serpentinised metamorphic peridotite*<sup>12</sup>: a black, massive serpentised harzburgite with 5–20% orthopyroxene pseudomorphs shows incomplete serpentisation of olivine, usually with up to 10% relicts. Disseminated chromite is present, as well as podiform chromite lenses up to 20 cm thick. Near the contact with the mélangé, the peridotite is intensely sheared, partly carbonitised and veined by magnesite. (iii) *Serpentinised cumulate peridotite*<sup>12</sup>: the boundary between these

and the serpentised harzburgite has not been mapped in the field. The cumulate peridotites are recognised in thin sections which show serpentised wehrlite with 50% clinopyroxene. Near the imbricate fault zone, thin (up to 30 cm) yellow-weathering layers were seen in the field which proved in thin section to be serpentised dunites. The cumulate peridotite is about 400 m thick adjacent to and south of the imbricate fault zone. The combined thicknesses of the two peridotite zones (ii and iii) is about 1.2 km. (iv) *The imbricate fault zone* is a striking and mappable unit in the field. It is up to 200 m wide and consists of a series of near-vertical fault slices from 1 to 15 m thick of light-coloured meta-gabbro and brown sheared serpentinite.

The meta-gabbro slices rarely show igneous layering and this is truncated by the faults. Usually the meta-gabbro is partly mylonitised so that blocks retaining gabbroic texture are found set in a pale, streaky, mylonitised host. Some of the thinnest fault slices (about 1 m thick) are made up entirely of mylonitised meta-gabbro and lack relict textures. This zone may have faulted out melanocratic layered gabbro as blocks of this rock are

present in the mélange. (v) *Layered gabbro*: a leucocratic gabbro with varying amounts of alteration shows a poorly-developed, rhythmic layering, but clear igneous lamination. Typically areas of pegmatitic-textured gabbro and aphyric meta-dolerite dykes are present. The layered gabbro is poorly represented in the mapped area but occurs within the imbricate fault zone and the sheeted dyke complex. Fault-bounded blocks of gabbro occur in

the north of the mapped area. Many outcrops show all stages of deformation of the gabbro from flaser gabbro to brecciated meta-gabbro set in a mylonitised host. (vi) *The sheeted dyke complex*: most of the complex consists entirely of meta-dolerite dykes. These have a distinctive, aphyric, doleritic texture and a green colour. The distinctive texture allows chilled margins to be recognised. Individual dykes range from 30 cm to 2 m in width. The thickness of this complex varies from 200 to 600 m. The field separation of meta-lavas from meta-dykes is easy as the lavas are much finer grained, contain sparse amygdaloids and weather brown. In the centre of the mapped area, the upper and lower boundaries of the sheeted-dyke complex are transitional over distances of up to 50 m. Along the upper contact some zones of 50% each of dykes and lavas have been mapped (Fig. 1a). Where there is <20% dykes the rocks were mapped as lavas. A striking feature of the upper half of the sheeted dyke complex is the presence of many brown and white patches and areas up to a few metres in size, where the dykes show evidence of metasomatic leaching and iron staining. The orientation of the pillow lavas adjacent to the sheeted dyke complex is near vertical or steeply inclined towards the north. The sheeted dykes immediately below the lavas are orientated at right angles to the lava stratification. Adjacent to the gabbro some of the dykes are now steeply inclined, indicating they were originally at low angles relative to the stratification of the lavas. (vii) *Meta-basalt lavas*: the sheeted dyke complex is overlain by a succession dominated by meta-basalt lavas, at least 300 m thick, but repeated by folding and faulting. Most of the lavas occur as thin-skinned pillow lavas with pale-brown, fine-grained cores and narrow, black-green, chloritised selvages, although a thick-skinned type is sparsely present (Fig. 1). This latter type is characterised by individual pillows having outer chill zones up to 8 cm thick which contain an abundance of white spherulites up to 4 mm in diameter. The cores of this type of pillow are composed of the normal meta-basalt. Almost all of the meta-lavas are aphyric, although one occurrence of plagioclase-aphyric pillow lava was found. Many of the pillows have a tubular form. Some horizons of brecciated pillow lava occur and probably indicate palaeoslopes. (viii) *Shale and laminated chert*: within the meta-basalt sequence, there is a single meta-sedimentary unit up to 50 m thick. This consists of thin-bedded, fissile, khaki-coloured shale with some colour variations which indicate the stratification. Within this unit some shale horizons are siliceous and pass into thin units (<1 m thick) of laminated chert. (ix) *Plagiogranite*: a single arcuate (folded?) and fault-bounded block of plagiogranite is present in the much-faulted northern part of the mapped area (Fig. 1a). The plagiogranite is crosscut by dykes of pink Pan-African granite. The mineralogy is essentially quartz and sodic plagioclase ( $An_{10}$ ). The plagioclase is turbid and there is a small amount of a chloritised mafic mineral. (3) *The upper meta-volcanic sequence* is lightly metamorphosed and consists of andesite, dacite and rhyolite lavas with sparse occurrences of pillowed meta-basalt lavas. The latter are distinct in being highly amygdaloidal in contrast to the very sparsely amygdaloidal pillow lavas of the ophiolite complex. Clastic rocks are abundant in the upper meta-volcanic sequence. Most prominent are rhyolitic lithic tuffs and multilithologic submarine slump deposits containing conspicuous rhyolite blocks up to 1.5 m in diameter. The environment of deposition evidently varied from shallow-water submarine to subaerial as some horizons have shales with mudcracks and at another welded tuffs are present.

## Structure and tectonism

The Jabal Ess ophiolite complex occurs as a syncline with the gabbro-serpentine components repeated in the north and the south of the mapped area (Fig. 1a). The abundance of pillow lava structure has been used to indicate the way up. The study (Fig. 1a and b) showed that the meta-basalt lavas are repeated by folding about the synclinal axis. The ophiolite complex is discordantly fault-separated from the overlying upper meta-

volcanic sequence. The faults are distinct because on Jabal Ess the upper meta-volcanic sequence is juxtaposed onto the serpentinised peridotite and then, towards the east, onto successively higher structural units of the ophiolite complex. The faults are carbonitised and locally silicified. This alteration along faults is best developed on Jabal Ess where up to 20 m of serpentinite have been carbonitised.

The base of the ophiolite complex is the bottom of the mélange zone which is concordant with the meta-sedimentary sequence. The latter concordantly contains lenses of mélange up to 10 m thick. The mélange zone presumably represents an original low-angle thrust fault zone which must have cut across all units of the ophiolite complex, as indicated by the content of blocks within the mélange. The Jabal Ess ophiolite complex is interpreted as an allochthonous fault slice which was emplaced by thrusting to concordantly overlie the meta-sedimentary sequence. Significantly, there are no clasts from the upper meta-volcanic sequence within the mélange. This absence suggests that the discordant set of faults, which mark the upper boundary of the ophiolite complex, postdate the basal thrust of the mélange zone.

The ophiolite complex, together with its host rocks, has been twice folded. Both folding events seem to postdate the emplacement of the allochthonous slice as well as the juxtapositioning of the ophiolite complex and upper meta-volcanic sequence. The first folding formed a tight syncline with an east-west fold axis. A later folding event resulted in more open folds about NNW axes, so that the ophiolite complex has a sigmoidal form. The combination of the two folding events has resulted in near-vertical dips for most of the mapped area and the basal mélange zone of the ophiolite complex is now overturned. Only the main faults are shown on the map (Fig. 1a).

## Conclusions

We have confirmed that Proterozoic ophiolite complexes in the sense of the Penrose meeting do exist in the Saudi Arabian Shield. Metamorphism has not obliterated the original rock features in this occurrence, which can be used as a type locality for Arabian Proterozoic ophiolites. The area is readily accessible by road or light aircraft. The recognition of such units as the aphyric sheeted dyke complex will identify similar rocks in other more tectonised areas of the shield.

The presence of an allochthonous thrust slice of Proterozoic ophiolite within the shield is a strong indication that plate-tectonic motions operated during the late Proterozoic. This conclusion strongly supports an accretionary type of model for the crustal evolution of the large igneous terrain of the Arabian Shield.

This work forms part of a PhD project (M.S.) at the King Abdul Aziz University. We thank H. E. Sheikh G. Sultan, Dr A. Al-Shanti and Dr J. Altmann and other members of the B.R.G.M. for approval and logistical support, also Colin Ramsay for helpful comments. This work is a contribution to IGCP Project 164.

# Modulation of the two promoters of the galactose operon of *Escherichia coli*

Sankar Adhya & William Miller

Laboratory of Molecular Biology, National Cancer Institute, NIH, Bethesda, Maryland 20014

*The gal operon of Escherichia coli is controlled by two independent promoters—one is activated and the other inhibited by cyclic AMP and cyclic AMP receptor protein. The two promoters are modulated, however, by the same operator locus and repressor protein.*

THE galactose (*gal*) operon of *Escherichia coli* consists of three structural genes, *K*, *T* and *E*, with the promoter-operator (*P*-*O*) located at the *E* end of the transcriptional unit<sup>1</sup> (Fig. 1). In wild-type *E. coli* cells, expression of the *gal* genes is inducible by D-galactose or D-fucose<sup>2</sup>. The inducer prevents a specific repressor protein, the product of the unlinked *galR* gene, from binding to the *gal* operator<sup>3</sup>. The operator has been defined genetically by the isolation of *cis* dominant mutations, which map to the right of the *E* gene and make *gal* expression constitutive.

It has been shown both *in vivo* and *in vitro* that the *gal* operon is controlled by two promoters: *P*<sub>1</sub> and *P*<sub>2</sub><sup>4</sup>. The *P*<sub>1</sub> promoter requires cyclic AMP and cyclic AMP receptor protein (CRP) as positive control elements for its activity; *P*<sub>1</sub> is normally responsible for *gal* expression in wild-type cells. The *P*<sub>2</sub> promoter does not need the cyclic nucleotide and the receptor protein and is in fact inhibited by the presence of the two regulatory elements. The *in vitro* startpoints of transcription from the two *gal* promoters, *S*<sub>1</sub> and *S*<sub>2</sub>, are also different and separated by five nucleotides (Fig. 1)<sup>4</sup>. In normal conditions of *in vitro* transcription, that is, in the presence of excess nucleoside triphosphate precursors, transcription from *P*<sub>2</sub>, starting at *S*<sub>2</sub>, largely terminates after completing a trinucleotide leader RNA. The reason for this premature termination is not clear and will be touched upon later.

We report in this article that the synthesis of *gal* enzymes under *P*<sub>2</sub> control, like that under *P*<sub>1</sub>, is also inducible and is under the negative control of the *galR* gene product. The same DNA segment in *gal*, defined by the *O*<sup>c</sup> mutations and by *in vitro* *gal* repressor binding experiments, is required for inhibition of both *P*<sub>1</sub> and *P*<sub>2</sub> activities. The accompanying article<sup>5</sup> shows that the location of the *gal* operator with respect to the *gal* promoters differs markedly from other known promoter-operator structures (Fig. 1).

## Induction of *gal* operon

In wild-type *E. coli* cells, under conditions of high cyclic AMP levels, the *gal* enzymes are made almost entirely from the *P*<sub>1</sub> promoter, whereas in cells deficient in cyclic AMP or CRP, the *P*<sub>2</sub> promoter is responsible for the expression of the operon. Thus, the regulatory features of the two promoters can be studied separately simply by measuring the *gal* enzymes made in *cya*<sup>+</sup>*crp*<sup>+</sup> and *cya*<sup>-</sup> (or *crp*<sup>-</sup>) strains, respectively. Evidence that both promoters are not on together *in vivo* in the presence of inducer and cyclic AMP-CRP is provided by the finding that the *P*<sub>1</sub><sup>-</sup> mutation is Gal<sup>-</sup> in *cya*<sup>+</sup>*crp*<sup>+</sup> strains. Table 1 compares the effect of the *gal* inducer D-galactose on the two promoter activities as measured by galactokinase synthesis, the product of the *galK* cistron, in the two strains SA500 (wild type) and SA1039 (*cya*<sup>-</sup>). Clearly, both the promoters are inducible. This is the first experimental evidence that *galP*<sub>2</sub> is inducible; previous measurements of *gal* induction and repression reflected *gal* expression controlled by *P*<sub>1</sub>, the cyclic AMP dependent

promoter. It should be noted that the actual levels of galactokinase, the last gene product, made from a promoter need not reflect the strength of that promoter. It is possible that the two promoters might show different degrees of natural polarity (S. A. and S. Gottesman, in preparation).

However, similar galactokinase induction ratios (about 15-fold) with the two promoters and the fact that both *P*<sub>1</sub> and *P*<sub>2</sub> activities can be induced by the same inducers, D-galactose (Table 1) and D-fucose (data not shown), suggest that *P*<sub>2</sub> is controlled by the same repressor molecule that controls *P*<sub>1</sub>, that is, the *galR* gene product. This was corroborated as follows. The *cya*<sup>-</sup> mutation of SA1039 was introduced into a set of strains, isogenic with wild type strain (SA500), which harbour a series of *galR* mutations. Comparison of galactokinase levels between the corresponding *galR*<sup>-</sup>*cya*<sup>+</sup> and *galR*<sup>-</sup>*cya*<sup>-</sup> strains showed constitutive synthesis in each case, including a *galR* deletion strain (Table 1). The *galR*<sup>-</sup> mutations have previously been shown to be recessive to the *galR*<sup>+</sup> allele<sup>6</sup>.

Identical negative control of both the promoters by the same *gal* repressor was confirmed by studying the effect of a *galR*<sup>S</sup> mutation on *P*<sub>1</sub> and *P*<sub>2</sub>. A *galR*<sup>S</sup> mutation has been shown to produce a non-inducible phenotype in a wild-type background and is dominant over *galR*<sup>+</sup> (refs 1, 7). The phenotype is the result of the altered repressor protein, which fails to interact with the inducer molecule. The *galR*<sup>S</sup><sub>78</sub> mutation retains its phenotype in a *cya*<sup>-</sup> background, that is, galactokinase synthesis remains at the low basal levels both in *cya*<sup>+</sup>*galR*<sup>S</sup> (SA1796) and *cya*<sup>-</sup>*galR*<sup>S</sup> (SA1800) strains in the presence or absence of D-galactose (Table 1).

However, it is conceivable that the non-inducible Gal<sup>-</sup> phenotype of the *cya*<sup>-</sup>*galR*<sup>S</sup> strain is the result of the lack of an effective permease for D-galactose transport into the cell. This

**Fig. 1** Map of the *gal* operon, showing the operator mutations. *K*, *T* and *E* are the structural genes<sup>1</sup>. *P*<sub>1</sub> and *P*<sub>2</sub> are the two promoters, whose positions relative to each other are not known. There may be considerable overlap between the two loci, except that *P*<sub>1</sub> mutations do not affect the *P*<sub>2</sub> activity<sup>4</sup>. *S*<sub>1</sub> and *S*<sub>2</sub> represent startpoints of transcription for their corresponding promoters *P*<sub>1</sub> and *P*<sub>2</sub>. As shown, the *S*<sub>2</sub> transcript frequently terminates after synthesising a trinucleotide. The operator segment shows the nucleotide sequence together with the base pair changes of the six *O*<sup>c</sup> mutations<sup>5</sup>. The map is not drawn to scale.

**Table 1** Effect of repressor on *gal* promoters

Strains		Active promoter	Levels of galactokinase*	
No.	Genotype		-Galactose	+Galactose
SA500	Wild type	<i>P1</i>	0.9	15.7
SA1039	<i>cya</i> <sup>-</sup>	<i>P2</i>	0.6	9.0
SA1857	<i>galR</i> <sub>3</sub> <sup>-</sup>	<i>P1</i>	8.5	7.8
SA1858	<i>galR</i> <sub>3</sub> <sup>-</sup> <i>cya</i> <sup>-</sup>	<i>P2</i>	14.4	11.0
SA1859	<i>galR</i> <sub>B78</sub> <sup>-</sup>	<i>P1</i>	8.3	7.3
SA1860	<i>galR</i> <sub>B78</sub> <i>cya</i> <sup>-</sup>	<i>P2</i>	10.8	7.4
SA1260	<i>galR</i> <sub>Δ</sub>	<i>P1</i>	11.8	12.5
SA1775	<i>galR</i> <sub>Δ</sub> <i>cya</i> <sup>-</sup>	<i>P2</i>	20.6	12.0
SA1796	<i>galR</i> <sub>78</sub> <sup>S</sup>	<i>P1</i>	0.3	0.4
SA1800	<i>galR</i> <sub>78</sub> <sup>S</sup> <i>cya</i> <sup>-</sup>	<i>P2</i>	1.4	0.9
SA1953	<i>galR</i> <sub>78</sub> <sup>S</sup> <i>cya</i> <sup>-</sup> <i>lacP</i> <sub>uv5</sub>	<i>P2</i>	0.7	0.7

Galactokinase was assayed in lysed cells after 2 h of log phase growth in minimal M56 media containing 0.3% D-fructose as carbon source, 0.1% casaminoacids and 0.3% D-galactose as inducer when indicated. Cells were lysed by 0.1 M Tris-HCl, pH 7.9, 0.1 M EDTA and 0.03 M dithiothreitol plus a drop of toluene at 37 °C for 15 min. The wild-type strain, SA500, is F<sup>-</sup> *str*<sup>R</sup> *his*<sup>-</sup> *rel*<sup>-</sup>. All others were derived from SA500. The *galR*<sub>Δ</sub> also deletes the adjacent *lysA* region<sup>14</sup>. The *galR*<sub>78</sub><sup>S</sup> (ref. 1) mutation was introduced into the *galR*<sub>Δ</sub> strain by phage P1 selecting for *lys*<sup>+</sup> and screening for *galR*<sub>78</sub><sup>S</sup>. The galactokinase assay procedure is from Wilson and Hogness<sup>15</sup>.

\*Units: nmol galactose-1-phosphate generated per min by the number of cells equivalent to A<sub>540</sub> of 1.0.

objection was ruled out as follows. Lactose permease, the product of the *lacY* gene, efficiently transports D-galactose<sup>6</sup>. Active *lac* enzymes can be synthesised in a *cya*<sup>-</sup> strain when the *lac* operon carries the *uv5* promoter mutation<sup>8</sup>. Accordingly, the strain *galR*<sub>78</sub><sup>S</sup> *cya*<sup>-</sup> was made into *galR*<sub>78</sub><sup>S</sup> *cya*<sup>-</sup> *lacP*<sub>uv5</sub> to ensure an effective D-galactose transport by selecting for Lac<sup>+</sup> transductant after infection of a bacteriophage P1 lysate made on a *cya*<sup>-</sup> *lacP*<sub>uv5</sub> host. Table 1 shows that similar to *galR*<sub>78</sub><sup>S</sup> *cya*<sup>-</sup> (SA1800) parent, the triple mutant *galR*<sub>78</sub><sup>S</sup> *cya*<sup>-</sup> *lacP*<sub>uv5</sub> (SA1953) is still non-inducible for galactokinase. Taken together, the results with the *galR* mutants convincingly show that the same repressor molecule controls *gal* expression negatively both in the absence and presence of cyclic AMP, that is, both from the *P1* and *P2* promoters.

## The *gal* operator

Using a strain diploid for the *galR*<sup>+</sup> gene, that is, *galR*<sup>+</sup>/*galR*<sup>+</sup>, several *E. coli* mutants constitutive for the *gal* operon were isolated after UV mutagenesis and then enrichment and selection for growth on galactose minimal media in the presence of an anti-inducer of the operon, methyl-β-D-thiogalactoside as previously described<sup>3,6,10</sup>. The *galR*<sup>+</sup> diploid was made by lysogenising wild type strain SA500 with a *λgalR*<sup>+</sup> transducing phage isolated before<sup>9</sup>. Many such mutants carry *cis*-dominant, *gal*-linked constitutive mutations (S.A., unpublished results). These mutations define the *gal* operator (the site of repressor action). Six such independently isolated operator constitutive mutations (*O*<sup>c</sup>), including one that was isolated previously in a *galR*<sup>+</sup> haploid strain<sup>3</sup>, were further characterised as follows:

(1) All six mutations, listed in Table 2, cause very high levels of galactokinase synthesis in the absence of any inducer. The same high levels of galactokinase were made even in the *cya*<sup>-</sup> derivatives of the *O*<sup>c</sup> mutants. If the *gal* operon in the *O*<sup>c</sup> mutants, as in the *O*<sup>+</sup> parent, is transcribed from the *P2* promoter in the absence of cyclic AMP, these results suggest that the same mutations are responsible for making the *gal* expression constitutive both from *P1* and from *P2*.

(2) The levels of galactokinase in four of the six *O*<sup>c</sup> mutants, *O*<sub>81</sub><sup>c</sup>, *O*<sub>1038</sub><sup>c</sup>, *O*<sub>1033</sub><sup>c</sup> and *O*<sub>1036</sub><sup>c</sup>, cannot be further increased by the addition of D-galactose to the growth media under conditions of both *P1* and *P2* activities. This contrasts the *galO*<sup>c</sup> mutants with

*O*<sup>c</sup> mutants in other operons, which usually can be further induced. The behaviour of the *galO*<sup>c</sup> mutants may be attributed perhaps to the demand of the selection procedure used.

(3) The levels of galactokinase in the same four *O*<sup>c</sup> mutants are significantly higher than that in the fully induced *O*<sup>+</sup> cells. This is true, both in *cya*<sup>+</sup> and *cya*<sup>-</sup> backgrounds. The *galO*<sup>c</sup> mutants are, in these respects as well, unique. We have considered three possibilities to explain the hyperactivity of the *galO*<sup>c</sup> mutants: (i) The *galO*<sup>c</sup> mutations have in fact created new cyclic AMP-dependent promoters, transcription from which is not repressible by the *gal* repressor. This may also explain property (2) described above. (ii) The two *gal* promoters and the *gal* operator sequences overlap such that the *O*<sup>c</sup> mutations increase the efficiency of the promoters. (iii) The natural polarity observed in the *gal* operon, that is, synthesis of reduced amount of product from the promoter-distal *K* gene (S. A. and S. Gottesman, in preparation), is eliminated by the *O*<sup>c</sup> mutations in an unknown way. Elimination of natural polarity would increase the levels of galactokinase. *gal* DNA templates, carrying either *O*<sup>+</sup> or one of the six *O*<sup>c</sup> alleles, behave identically in a purified transcription system, that is, they need cyclic AMP for transcription from the *P1* promoter but not from *P2* (refs 5, 11). The latter was always inhibited by the presence of cyclic AMP and CRP. These results do not rule out, but argue against possibility (i). We are now studying possibilities (ii) and (iii).

(4) The accompanying article<sup>5</sup> shows the base-pair alterations of the six *O*<sup>c</sup> mutations in the *gal* control region (indicated in Fig. 1). All six mutations cluster in a small region (spanning seven bases). This segment is located about 60 nucleotides upstream from the start site of the S1 transcript. The short length of the *galO* segment and the fact that two of the mutations, *O*<sub>1033</sub><sup>c</sup> and *O*<sub>1036</sub><sup>c</sup>, show identical base-pair changes and two others (*O*<sub>1034</sub><sup>c</sup> and *O*<sub>1035</sub><sup>c</sup>) affect the same base pair suggest uniqueness of the operator structure. [Note that half of the mutations show simultaneous change of two adjacent base pairs. This may be attributed to the nature of the mutagen used (UV light) to induce the mutations. UV light has been shown to cause similar tandem base-pair changes in other *E. coli* genes<sup>12</sup>.]

## Discussion

The *gal* operon of *E. coli* is unique in that the same structural genes are controlled by two natural promoters. *P1* and *P2* meet the additional requirements of galactose enzymes for anabolic reactions under extreme physiological conditions—excess or deficiency of cyclic AMP. The results discussed above show that both promoters are subject to repression. The same regulatory elements, *gal* repressor, D-galactose and the *gal* operator, control the *gal* expression from both *P1* and *P2*. A contrasting feature of the two promoters is that one (*P1*) is activated and the other (*P2*) inhibited by cyclic AMP and its receptor protein. For *P2*, cyclic AMP and CRP together are not co-repressors acting

**Table 2** Effect of operator mutations on the *gal* promoters

Operator allele	Levels of galactokinase in			
	<i>cya</i> <sup>+</sup>		<i>cya</i> <sup>-</sup>	
<i>O</i> <sup>+</sup>	-I	+I	-I	+I
<i>O</i> <sub>81</sub> <sup>c</sup>	1.0	18.0	0.7	8.1
<i>O</i> <sub>1038</sub> <sup>c</sup>	31.1	36.1	30.5	29.6
<i>O</i> <sub>1033</sub> <sup>c</sup>	32.0	34.3	34.0	32.0
<i>O</i> <sub>1036</sub> <sup>c</sup>	34.0	33.4	36.0	31.3
<i>O</i> <sub>1034</sub> <sup>c</sup>	33.1	34.2	34.6	32.0
<i>O</i> <sub>1035</sub> <sup>c</sup>	9.2	14.9	26.0	29.2
<i>O</i> <sub>1035</sub> <sup>c</sup>	31.2	31.3	15.0	29.4

The *O*<sup>+</sup> strain is SA500 described in Table 1. The strains are isogenic with SA500. The *cya*<sup>-</sup> mutation was transduced into the *O*<sup>c</sup> mutants with phage P1 by selecting for a *val*<sup>R</sup> marker and screening for Lac<sup>-</sup> phenotype. The *val*<sup>R</sup> marker is 40% co-transducible with the *cya*<sup>-</sup> allele (A. Das, unpublished results). The other details are also described in Table 1. -I and +I indicate the absence and presence of D-galactose (inducer) during cell growth.

in concert with the *gal* repressor, because *crp*<sup>-</sup> mutants do not make the *gal* enzymes constitutively. The molecular mechanisms of action of CRP have been explored and are discussed in the accompanying article<sup>5</sup>.

We have shown above that the *gal* repressor represses *gal* transcription from both *P1* and *P2* by acting at the same operator site, as defined by *O*<sup>c</sup> mutations. *In vitro gal* transcription from the *P1* promoter in a purified system in the presence of cyclic AMP and CRP is inhibited by the addition of the *gal* repressor<sup>11</sup>. As expected, the *gal* repressor failed to show repression when the template DNA carried any one of the six *O*<sup>c</sup> mutations discussed above<sup>5,11</sup>. In repressing the *P1* promoter, *gal* repressor acts in a manner competitive with RNA polymerase plus CRP<sup>13</sup>. However, the mechanism of action of *gal* repressor may be different from simple competition, because the operator is located at an unusual site—well upstream from the RNA polymerase or CRP binding site. The synthesis of the

short S2 transcripts made from the *galOP* restriction fragment in the absence of cyclic AMP and CRP (that is, under the control of the *P2* promoter), however, is not inhibited by the *gal* repressor<sup>5</sup>. The *gal* repressor may fail to repress S2 synthesis in the purified transcription system for at least two possible reasons. (1) Lack of an additional element besides the *gal* repressor is needed for repression of *P2* activity. And (2), *gal* transcription from the *P2* promoter is not controlled by inhibition of initiation, but by elongation of the short S2 transcript. The *gal* repressor might act by inhibiting the elongation of S2 RNA.

We are currently investigating these possibilities in order to explain the above discrepancy between *in vivo* and *in vitro* control of the *gal* operon.

We thank M. Irani, M. Gottesman, A. Das, R. DiLauro, and B. de Crombrughe for discussions.

# Unusual location and function of the operator in the *Escherichia coli* galactose operon

Roberto DiLauro\*, Taketoshi Taniguchi, Richard Musso† & Benoit de Crombrughe

Laboratory of Molecular Biology, National Cancer Institute, Bethesda, Maryland 20205

*The operator of the gal operon is located about 60 base pairs preceding the startpoints of the transcription of the two gal promoters. This location contrasts with the location of the operator in other phage or bacterial operons where the repressor binds more closely to the respective transcription initiation sites. Models explaining how the repressor-operator interactions may control the two gal promoters are presented.*

OUR previous studies have shown that two overlapping promoters control the expression of the galactose operon of *Escherichia coli*. *In vitro* transcription experiments of a DNA fragment containing the *gal* operator–promoter region demonstrated that cyclic AMP and its receptor protein (CRP) were required for the activity of one promoter (*P1*), but inhibited transcription at the other promoter (*P2*)<sup>1</sup>. The transcription initiation site for *P2* precedes the startpoint for *P1* by five base pairs in the DNA sequence. We presented arguments which strongly suggest that these two promoters are active *in vivo* under different physiological conditions<sup>1</sup>.

In addition to this dual cyclic AMP–CRP regulation, the *gal* operon is also controlled by the *gal* repressor, the product of the *galR* gene which is unlinked to the *gal* operon<sup>2,3</sup>. Earlier studies had shown that the *gal* repressor binds specifically and with a

very high affinity to *gal* DNA<sup>4</sup> and blocks *gal* transcription *in vitro* with wild-type *gal* DNA but not with *gal* DNA with operator-constitutive mutations<sup>5</sup>. We report here on the effect of the *gal* repressor at each of the two *gal* promoters, and on the unusual location of the repressor binding site.

By sequencing five *gal* operator mutations we show that the repressor binds about 60–65 base pairs upstream from the startpoint for cyclic AMP–CRP dependent transcription. This contrasts with the location of the operator in the *lac*<sup>6</sup>, *trp*<sup>7</sup> and *lambda* operons. In the latter systems the repressor binds much more closely to the respective initiation sites for transcription and probably directly prevents the stable binding of RNA polymerase to the promoters. The location of the *gal* operator suggests that in *gal* the repressor prevents transcription by a different mechanism.

We also show that in our purified *in vitro* transcription system the *gal* repressor inhibits transcription from *P1*; it does not block initiation of transcription at *P2* in the absence of cyclic AMP–CRP and does not prevent the cyclic AMP–CRP dependent inhibition of *P2*. In contrast, *in vivo* results presented in the accompanying article<sup>9</sup> indicate that both *P1* and *P2* are under repressor control. Possible explanations for this discrepancy as well as models for the mechanism of action of the *gal* repressor will be discussed.

## Sequence changes in *galO*<sup>c</sup> mutants

We have examined five *gal*-linked *cis*-dominant mutants which exhibit a high constitutive rate of synthesis of the *gal* enzymes. Several lines of evidence indicate that these *gal* mutations define a site to which the *gal* repressor binds (see also accompanying article<sup>9</sup>). (1) The mutants were selected as capable of growing in

† Present address: National Cancer Institute, Frederick Cancer Research Center, Frederick, Maryland 21701.

**Table 1** The presence of a plasmid harbouring a wild-type or mutant *gal* operator affects expression of the chromosomal *gal* genes

Strain	Genotype of <i>gal</i> operator in plasmid	Galactokinase (units)	
		-D-fucose	+D-fucose
MR94	I	2.8	24.8
MR94/pBdC1	O <sup>+</sup>	18.1	36.9
MR94/pBdC6	O <sup>c</sup>	4.7	20.5

Plasmid pBdC1 is derived from pBR322 in which the 30 base pair fragment between the unique *Eco*RI and *Hind*III sites of pBR322 has been replaced by an *Eco*RI-*Hind*III fragment derived from  $\lambda$ gal8 DNA<sup>21</sup>. The inserted fragment has a size of about 1,000 base pairs and contains the operator-promoter region of the *gal* operon and about 450 base pairs of the first *gal* cistron (B.deC., in preparation). pBdC1 contains a wild-type *gal* operator whereas pBdC6 contains the O<sub>81</sub><sup>c</sup> *gal* mutation (see Fig. 4a). Medium for growth of cells and assay conditions for galactokinase were as described previously<sup>1</sup>. MR94 is a *recA* derivation of MR93 (collection of E. Singer) constructed by C. B. Bruni.

a minimal galactose medium in the presence of the anti-inducer of the *gal* operon, methyl- $\beta$ -D-thiogalactoside (TMG), a property which is also common to *galR* mutants<sup>10</sup>. Presumably, in both types of mutants no stable *gal* repressor-operator complex is formed, thus expression of the operon is constitutive and these cells can grow in a minimal salts medium containing galactose plus TMG. (2) Earlier *in vivo* transcription studies with  $\lambda$  *gal* DNA showed that the *gal* repressor blocks cyclic AMP-CRP dependent *gal* mRNA synthesis (as measured by DNA-RNA hybridisation) with wild-type *gal* DNA but not with the DNA from a *galO*<sup>c</sup> mutant<sup>5</sup>. (3) We have constructed a plasmid (derived from pBR322) which contains the *gal* operator-promoter region and the promoter proximal third of the *galE* cistron (B.deC., manuscript in preparation). Wild-type cells transformed with this plasmid are also capable of growing in minimal galactose plus TMG. The 30 or more copies of *gal* operator titrate the *gal* repressor and cause the constitutive 'escape' expression of the chromosomal *gal* genes. If a *galO*<sup>c</sup> mutation is introduced in the plasmid, the cells are incapable of growing on minimal galactose plus TMG and exhibit a normal induction pattern of *gal* enzyme synthesis (Table 1). We can assume that, unlike the parent plasmid, the plasmid with a *galO*<sup>c</sup> mutation is unable to titrate the cellular *gal* repressor. Hence, the mutation marks the repressor binding site in the *gal* regulatory region.

We have previously established a restriction map for the regulatory DNA segment preceding the first *gal* structural gene<sup>11</sup>. Figure 1 shows the restriction sites of interest. Endonuclease *Hinf* cleaves wild-type *gal* DNA 60/59 base pairs (on the I strand) preceding S1, the startpoint for cyclic AMP-CRP dependent transcription. With two of the mutants (O<sub>1034</sub><sup>c</sup> and O<sub>1035</sub><sup>c</sup>) the DNA is not cleaved by *Hinf* at this site (data not shown), suggesting that these mutations may lie within the recognition site for *Hinf* endonuclease.

The base changes for each of five mutants were determined. The sequence data are detailed below. The 35 base pair DNA fragment 1 (see Fig. 1) from mutant O<sub>81</sub><sup>c</sup> was labelled selectively at its *Hinf* 5' end and digested by snake venom phosphodiesterase. The partial exonuclease digestion products of the mutant fragment and of a similarly treated wild-type DNA fragment were mixed and fractionated by two-dimensional fingerprint analysis<sup>19</sup>. Figure 2a compares the mobility shifts of the fractionation products of the mutant fragment with those of the wild-type fragment. The patterns deviate at the site of the mutation indicating that the C residue (-66) in the wild-type sequence<sup>19</sup> is replaced by a T residue in the mutant. Immediately following the mutated residue the succession of mobility shifts runs parallel in the mutant and in the wild-type pattern. Hence no other base change occurs adjacent to the first mutation. That the new shift in the mutant is caused by a T residue and not by a G is indicated by analysis of its mobility shift and the mobility

**Fig. 1** Restriction map of the *gal* operator-promoter region. S1 is the startpoint for cyclic AMP-CRP dependent *gal* transcription, S2 is the startsite for cyclic AMP-CRP independent *gal* transcription. 1 and 2 refer to restriction fragments used for sequencing studies. The DNA sequence of the *gal* operator-promoter segment has been determined<sup>19</sup>.

shifts produced by the addition to known T and G residues in the wild-type sequence. Furthermore, when the same fragment I of mutant O<sub>81</sub><sup>c</sup>, also uniquely labelled at its *Hinf* 5' end, was treated with dimethylsulphate (DMS) according to the procedure of Maxam and Gilbert<sup>10</sup> and the fractionation products analysed by gel electrophoresis, it was clear that no new G residue appeared at position -66 (data not shown).

A similar analysis was applied to the DNA of mutant O<sub>1033</sub><sup>c</sup>. The two-dimensional fractionation of the partial nuclease degradation products of fragment I shows that two adjacent T residues in the wild-type sequence (-64 and -63) have been replaced by an A residue (-63) and a C residue (-64) (Fig. 2b). A DMS analysis on the same mutant fragment, labelled at the

**Fig. 2** Partial venom exonuclease digests of fragment 1 (of Fig. 1) terminally labelled at its *Hinf* 5' end from wild type and from the mutants O<sub>126</sub><sup>c</sup> and O<sub>1033</sub><sup>c</sup>. A fragment obtained by *Hinf* cleavage, which contains DNA to the left of the *Hinf* site in Fig. 1, was prepared as in ref. 11. This fragment was purified from  $\lambda$ gal8 DNA<sup>21</sup> (wild type) or its isogenic derivatives containing the O<sub>126</sub><sup>c</sup> or the O<sub>1033</sub><sup>c</sup> mutation. The fragments were dephosphorylated with bacterial alkaline phosphatase, 5'-end labelled with [ $\alpha$ -<sup>32</sup>P]ATP using T4 polynucleotide kinase<sup>19</sup> and digested with endonuclease *Hha*I. The products were resolved on a 10% polyacrylamide gel, and fragment 1 of Fig. 1 was eluted from the gel as described elsewhere<sup>11</sup>. Wild-type or mutant fragment 1 (individually or in combination) was partially digested with venom exonuclease in the presence of trace amounts of DNase I and fractionated by electrophoresis on Cellogel in 8M urea at pH 3.5 followed by homochromatography<sup>19</sup>. a, O<sub>126</sub><sup>c</sup> DNA and wild-type DNA; b, O<sub>1033</sub><sup>c</sup> DNA.

*Hinf* 5' end, confirmed the presence of an A change at -63 (data not shown).

As indicated earlier, the DNAs of mutants  $O_{1034}^c$  and  $O_{1035}^c$  lack the *Hinf* cleavage site at -60/-59 and hence were not amenable to the same partial exonuclease analysis as the preceding mutants. Fragment 2 (*Hha*-1/*Hap*-1) was end-labelled at the 5' *Hha*-end for each of these two mutants and sequenced according to Maxam and Gilbert<sup>12</sup>. Figure 3a compares the fractionation products resulting from the DMS and hydrazine reactions of wild-type DNA and  $O_{1034}^c$  DNA. A single base substitution, A for G, occurs in the mutant DNA at -60. The base pair which is mutated in  $O_{1034}^c$  thus lies within the *Hinf* site.

In mutant  $O_{1035}^c$  the same G/C base pair (-60) is changed to a T/A base pair. Figure 3b shows the products of chemical fractionation of the *Hha*-1/*Hap*-1 fragment (fragment 2 of Fig. 1) for this mutant. Comparison with the wild-type sequence in Fig. 4 indicates the position of the base change.

A similar analysis was performed with the same *Hha*-1/*Hap*-1 DNA fragment of mutant  $O_{1038}^c$  (Fig. 3c). In this mutant two adjacent base pairs G/C and T/A have replaced the two adjacent A/T base pairs at -65 and -64.

Figure 4a summarises the results of the sequence analysis of the five mutants. The mutations which we examined are all clustered in a small segment between -66 and -60.

### Effect of *gal* repressor on *in vitro* transcription

*In vivo* experiments<sup>9</sup> indicate that the interactions between the *gal* repressor and the *gal* operator repress both *P1* and *P2*. We have also studied the effect of *gal* repressor on initiation of transcription *in vitro* at each of the two startpoints. When the 235 base pair *Hha*I fragment (see Fig. 1) is used as template and the transcription reactions are conducted at low nucleoside triphosphate concentrations, a characteristic pattern of small RNAs is obtained which results from the pausing of RNA polymerase early after initiation of transcription<sup>1</sup>. These small RNAs can be analysed by polyacrylamide gel electrophoresis. Transcription initiating at S1 generates a diagnostic pattern, which is strikingly different from the pattern produced when

**Table 2** Efficiency of transcription initiation at *P1* and *P2*

	Specific activity per UMP residue	
	in 3-nucleotide-long oligonucleotide	in 9-nucleotide-long oligonucleotide
+cyclic AMP-CRP	—	1,100
-cyclic AMP-CRP	5,700	—

Comparison of the efficiency of initiation at S1 and S2. The 235 base pair *Hha*I fragment of Fig. 1 was transcribed as described in the legend of Fig. 5, both in the absence and the presence of cyclic AMP; the RNA was then fractionated on an 18% polyacrylamide gel. From each lane the major RNA band (corresponding to a trinucleotide in the minus cyclic AMP reaction and to a nonanucleotide in the plus cyclic AMP reaction) was located by autoradiography, excised from the gel and counted. The trinucleotide and the nonanucleotide each contain two UMP residues.

transcription starts from S2. In the presence of cyclic AMP-CRP the majority of the *gal* transcripts pause at several points within the first nine bases of the 5' end of the cyclic AMP-CRP dependent *gal* mRNA<sup>1,22</sup>. In the absence of cyclic AMP-CRP, transcription from S1 is completely inhibited and instead is initiated five bases upstream and pauses within a different six-base sequence. The nucleotide sequence of the various short transcripts was previously established<sup>1</sup>. Figure 5 shows that in the absence of cyclic AMP and CRP the *gal* repressor does not cause inhibition of transcription (lane 2). Hence in the conditions of our *in vitro* reaction, the *gal* repressor is unable to prevent initiation of transcription from S2. This conclusion is also valid when transcription reactions are conducted at high nucleoside triphosphate concentrations (data not shown). We have in fact observed a small but consistent increase in S2 RNA synthesis by *gal* repressor preparations (Fig. 5 lane 2). This increase is reversible by D-fucose.

In the presence of cyclic AMP and CRP, however, the *gal* repressor blocks S1 transcription and this repression is overcome by the *gal* operon inducer D-fucose. Although the *gal* operator is located in a segment which shows striking sequence

**Fig. 3** Autoradiographs of DNA sequencing gels. Fragment 2 of Fig. 1 from either wild-type DNA or from the mutant DNAs  $O_{1034}^c$ ,  $O_{1035}^c$  or  $O_{1038}^c$  was <sup>32</sup>P-labelled at its 5' *Hha* end and was subjected to base-specific chemical degradation according to Maxam and Gilbert<sup>10</sup>. The reaction products were fractionated on 20% polyacrylamide gels in 7M urea. The arrows indicate the site of the mutations. a, Comparison of wild-type DNA and  $O_{1034}^c$  DNA; b,  $O_{1035}^c$  DNA; c,  $O_{1038}^c$  DNA.

similarities and lies at the same distance from the initiation site as the CRP binding site in the *lac* operon, addition of repressor does not prevent the cyclic AMP–CRP dependent inhibition of transcription from S2 (Fig. 5, compare lanes 4 and 5). Our experiments thus clearly show that if both the *gal* repressor and cyclic AMP–CRP are present the two *gal* promoters are strongly inhibited.

### Transcription of *gal* operator constitutive mutants

The isolation of mutants which do not bind cyclic AMP–CRP<sup>13</sup> as well as direct chemical protection experiments<sup>14</sup> have defined the CRP binding site in the *lac* operon ( $\sim -70$  to  $-50$ ). Examination of a similarly located segment in *gal* reveals important similarities both in sequence and in symmetry (see Fig. 4b). Since all *galO<sup>c</sup>* mutations which we examined lie within this region ( $-66$  to  $-60$ ), we determined whether these mutations affected the cyclic AMP–CRP regulation of one or the other *gal* promoter. With every *galO<sup>c</sup>* mutant transcription from S1 is still completely dependent on cyclic AMP–CRP, and transcription at S2 only initiates in the absence of cyclic AMP–CRP (data not shown). One *gal* mutant (*galO<sub>81</sub><sup>c</sup>*) was particularly interesting to study since the same base change G/C to A/T at  $-66$  occurs in a *lac* mutant<sup>13</sup> at exactly the same location with respect to the startpoint of transcription in *lac* and S1 in *gal*. These mutations in *lac* and *gal* also occupy the same location within a similar symmetrical sequence (see Fig. 4) that seems to be the CRP binding site in *lac*. In *lac* the mutation causes severe reduction of promoter activity. In *gal* the same mutation results in the constitutive expression of the *gal* operon *in vivo* both in the presence or absence of CRP or cyclic AMP. *In vitro* the CRP concentration dependence and the cyclic AMP concentration dependence for both *P1* activation and *P2* repression are identical whether *galO<sub>81</sub><sup>c</sup>* DNA or wild-type DNA are used as a template. Figure 6 shows the effect of cyclic AMP concentration of *P1* and *P2* transcription for both types of DNA. Hence the mutation does not affect cyclic AMP–CRP function in *gal* in contrast to its profound effect on CRP action in *lac*.

Fig. 4 a, Summary of the base changes caused by 5 different *galO<sup>c</sup>* mutations. b, Comparison of the *lac* CRP site with a similarly located segment in *gal*.

### Initiation at *P2* is more efficient than initiation at *P1*

In an effort to characterise the *P2* promoter further, we compared the efficiency of initiation of transcription at S1 and S2. The characteristic small RNAs corresponding to each promoter as well as the larger RNA, which extends to the end of the fragment, were eluted from the polyacrylamide gel. The RNA sequence of each of the small RNAs is known, and their relative molar yields were determined from the radioactivity of the eluted material ( $[\alpha\text{-}^{32}\text{P}]\text{UTP}$  was used in these experiments). The results shown in Table 2 indicate that in our experimental conditions transcription initiates at S2 about five times more efficiently than at S1.

### Transcription of *P1* and *P2* at high nucleoside triphosphate concentrations

We also compared the pattern of transcription from *P1* and *P2* at low and at high nucleoside triphosphate (NTP) concentrations. If high (150–200  $\mu\text{M}$ ) instead of low (10  $\mu\text{M}$ ) NTP concentrations are used for *in vitro* *gal* RNA synthesis from the *Hha*-230 base pair fragment, stuttering is no longer observed for cyclic AMP–CRP dependent transcription from S1: all transcripts are of large size and extend to the end of the fragment. In the absence of cyclic AMP–CRP using high NTP concentrations, however, a considerable proportion of transcripts originating at S2 still terminates within the sequence of the first 6 or 7 bases (Fig. 7). Hence the termination of transcription from S2 is not just a result of the low NTP concentrations, unlike the pausing observed for S1 transcripts, but may represent an additional regulatory mechanism. Figure 7 also shows that in these conditions, when glycerol was present, less termination and more read-through to the end of the fragment are observed. Glycerol was shown previously to stimulate *gal* transcription from S2 in the absence of cyclic AMP–CRP<sup>1,15</sup>.

### Functional interactions between cyclic AMP–CRP, *gal* repressor and *gal* DNA

The DNA sequencing results presented in this article mark the location of the *gal* operator. The base changes produced by five *O<sup>c</sup>* mutations which we examined all lie between residues  $-60$  and  $-66$ . We have summarised the evidence which indicates that these mutations alter the binding of *gal* repressor to *gal* DNA. Our data do not determine the extent or the size of the operator. A more complete definition of the *gal* operator will be obtained by direct protection experiments against chemical modification of the DNA and by the isolation and sequencing of additional mutants. Such experiments are in progress. Interestingly, in three of the mutants two adjacent base pairs have been changed. The high frequency of this type of mutation is probably due to the method of mutagenesis—UV light.

The location of the *gal* operator contrasts with the location of the operators in other operons. The *lac* repressor protects about 20–22 base pairs, between  $-3$  and  $+20$  (ref. 6). The *trp* repressor interacts with a segment which includes at least the portion between  $-5$  and  $-17$  (ref. 16). At each of two  $\lambda$  promoters,  $\lambda P_R$  and  $\lambda P_L$ , the *lambda* repressor binds with decreasing affinity to three adjacent operators. The  $\lambda$  operators which are closest to the respective initiation sites have the highest affinity for the repressor<sup>8</sup>. In each of these systems the repressor thus binds at close proximity to the transcription initiation site and thereby prevents directly RNA polymerase from forming a stable preinitiation complex. The location of the *gal* operator suggests a different mechanism for repression.

Examination of the CRP binding site in *lac* and a segment in *gal* located about the same distance from the cyclic AMP–CRP

**Fig. 5** Effect of the *gal* repressor on initiation of transcription at S1 and S2. The *gal* repressor was purified from an *E. coli* strain containing the plasmid pGR4, a derivative of plasmid pBR313<sup>18</sup> in which the *galR* gene was introduced by *in vitro* recombination (R. di L., unpublished results). The repressor was purified according to a published procedure<sup>5</sup>, except that the affinity chromatography step was substituted with chromatography on single stranded DNA cellulose (R. di L., unpublished). Transcription reactions were carried out in a final volume of 50  $\mu$ l containing 1  $\mu$ mol Tris-HCl (pH 7.9), 5  $\mu$ mol KCl, 0.15  $\mu$ mol MgCl<sub>2</sub>, 5 nmol EDTA, 5 nmol DTT, 2.5  $\mu$ g bovine serum albumin, 0.9  $\mu$ g CRP, 0.5  $\mu$ g RNA polymerase, and 20 ng of the 235 base pair *Hha*I fragment of Fig. 1. After 10 min of incubation at 37 °C, heparin 5  $\mu$ g was added to inactivate unbound RNA polymerase and transcription was started 1 min later by adding 5  $\mu$ l of a solution containing 1 mM ATP and 100  $\mu$ M each of GTP, CTP and [ $\alpha$ -<sup>32</sup>P]UTP (10–20 CI mmol<sup>-1</sup>). Where indicated, cyclic AMP (10 mmol), *gal* repressor (0.9  $\mu$ g) and D-fucose (1  $\mu$ mol) were added before the addition of heparin. After 10 min at 37 °C reactions were terminated by adding 0.25 ml of 0.1 M Tris-HCl pH 7.4, 0.2% SDS, 10 mg ml<sup>-1</sup> tRNA, and 10 mM EDTA. After extraction with phenol, the RNA was precipitated with ethanol, redissolved in 10 M urea, 0.025% bromophenol blue, 0.025% xylene cyanol FF and electrophoresed on an 18% polyacrylamide gel in 7 M urea<sup>11</sup>. Lanes 1–3: no cyclic AMP added; lane 1, no repressor; lane 2, repressor alone; lane 3, repressor and D-fucose. Lanes 4–6: cyclic AMP added; lane 4, no repressor; lane 5, repressor alone; lane 6, repressor and D-fucose. Numbers on the right of the figure indicate the size of the RNAs in nucleotides.

startsite of transcription shows striking similarities both in sequence and symmetry (see Fig. 4b). In *lac*, sequence data of CRP site mutants and chemical protection experiments indicate that the symmetry in Fig. 4b is probably recognised by CRP. In *gal* all *O*<sup>c</sup> mutants which we examined are clustered between –66 and –60, so lie within the same region. Hence one possible mechanism for *gal* repression could imply an interaction of the *gal* repressor with the same site which is recognised by CRP: the *gal* repressor could block *P1* transcription by simply preventing CRP binding to DNA. The following results, however, indicate that despite the similarities in sequence and symmetry CRP does not interact with this segment in *gal*. (1) All *O*<sup>c</sup> mutations which we have examined exhibit the same degree of stimulation of *P1* activity by cyclic AMP–CRP and inhibition of *P2* function by these factors as wild-type DNA. More quantitative data were

**Fig. 6** Comparison of cyclic AMP effects on *P1* and *P2* transcription for wild-type *gal* DNA and mutant *O*<sub>81</sub>*gal* DNA. Conditions for transcription and analysis of the transcripts on 18% polyacrylamide–7 M urea gels were as described in Fig. 5 legend. Radioactive bands, visualised by autoradiography specific either for *P1* or *P2* transcription, were excised from the gel and counted. A 9-nucleotide-long transcript is specific for *P1*, whereas a 6-nucleotide-long transcript is specific for *P2*. *a*, Wild-type *gal* DNA: ■, *P1* RNA; ●, *P2* RNA. *b*, *O*<sub>81</sub>*gal* DNA: □, *P1* RNA; ○, *P2* RNA.

obtained with one *galO*<sup>c</sup> mutant (*O*<sub>81</sub>). This mutation lies at the same location within the 'common' symmetry and causes the same base change as a *lac* CRP binding site mutation<sup>13</sup> (see Fig. 4). In the mutant *gal*, the cyclic AMP–CRP concentration dependency for *P1* activation (and for *P2* repression) is indistinguishable from that obtained with wild-type DNA. Thus a similar mutation which severely reduces CRP-dependent promoter activity in *lac* has no effect on this function in *gal*, indicating that unlike in *lac* this site is not essential for CRP function in *gal*. (2) Protection experiments indicate that CRP binds between –50 and –25 in *gal* DNA and not to the segment which is analogous to the *lac* CRP binding site (T.T. and B.deC., unpublished results). (3) Replacement of the DNA to the left of –60 with an unrelated DNA sequence does not change the concentration dependency for cyclic AMP–CRP stimulation of *P1* and repression of *P2* (T.T. and B.deC., unpublished results). Thus CRP is capable of activating gene transcription by interacting at a different location in different CRP-dependent promoters.

Our results clearly indicate that binding of the *gal* repressor to *gal* DNA does not prevent the inhibition of *P2* transcription by cyclic AMP–CRP. One possible explanation would postulate the existence of two binding sites for cyclic AMP–CRP, one for

*P1*-stimulation, the other for *P2* repression. *gal* repressor would interfere with the binding of cyclic AMP-CRP at one site, not at the other. An alternative hypothesis to explain both the stimulatory and inhibitory effects of cyclic AMP-CRP is that the

**Fig. 7** Effect of nucleoside triphosphate (NTP) concentrations on transcription from S1 and S2. Transcription reactions and polyacrylamide gel analysis were as in Fig. 5 except for the NTP concentrations as described below. [ $\alpha$ - $^{32}$ P]UTP ( $10$ – $20$  Ci mmol $^{-1}$ ) was used as radioactive precursor. Lanes 1 to 3: no cyclic AMP added. Lane 1: ATP  $100$   $\mu$ M, GTP, CTP and UTP each  $10$   $\mu$ M; lane 2: ATP, GTP, CTP and UTP each  $100$   $\mu$ M and  $20\%$  glycerol (v/v); lane 3: ATP, GTP, CTP and UTP each  $100$   $\mu$ M; lane 4: cyclic AMP added, ATP, GTP, CTP and UTP each  $100$   $\mu$ M.

interaction of cyclic AMP-CRP with a unique DNA binding site could create different protein-protein interactions which would facilitate the formation of a stable transcription initiation complex at *P1* and inhibit this reaction at *P2*. Our finding that the concentrations of both CRP and of cyclic AMP needed for half maximal stimulation of *P1* are identical to those which cause  $50\%$  repression of *P2* is consistent with the latter model. If we postulate such a unique and specific binding site for CRP, it is obvious that the *gal* repressor cannot simply prevent CRP from binding to this site, since CRP still inhibits *P2* transcription in the presence of *gal* repressor. We believe that *gal* repressor could block the productive interaction between CRP and RNA polymerase at *P1* without affecting the interaction between CRP and RNA polymerase at *P2*. We cannot exclude, however, that cyclic AMP-CRP interacts with RNA polymerase first and the cyclic AMP-CRP-RNA polymerase complex binds to *P1* requiring little or no specific interactions between cyclic AMP-CRP and DNA. The same cyclic AMP-CRP-RNA polymerase complex would be unable to bind to *P2*. The high specificity of binding of the cyclic AMP-CRP complex itself to *lac* DNA<sup>12,15</sup> and to *gal* DNA (T.T. and B.deC., unpublished observations) does not favour such an hypothesis.

*In vivo* the *gal* operon can be induced by galactose or fucose even when cyclic AMP or functional CRP are eliminated from the cells by mutation. Both *galR* $^{-}$  mutants and cells harbouring many copies of a plasmid which contains an intact *gal* operator exhibit high levels of galactokinase synthesis whether cyclic AMP or CRP are present or not (see accompanying article<sup>9</sup> and B.deC., unpublished observations). *galO* $^{c}$  mutants also show a high level of constitutive *gal* expression in the presence or absence of cyclic AMP-CRP. These *in vivo* results clearly indicate that the interaction between the *gal* repressor and the *gal* operator causes repression of both *P1* and *P2*. *In vitro*, however, the *gal* repressor blocks only the cyclic AMP-CRP dependent transcription from S1 but does not decrease initiation of transcription from S2. The repressor binds to *gal* DNA in the absence of cyclic AMP-CRP but does not prevent RNA polymerase from initiating transcription at S2. Hence, the *in vitro* results reproduce the *in vivo* regulation by the *gal* repressor when transcription starts from S1. In the absence of cyclic AMP or CRP, however, repression of *gal* transcription occurs *in vivo* but not, in our experimental conditions, *in vitro*. This could suggest that our defined *in vitro* system is lacking one or more elements responsible for the repression at S2 *in vivo*.

In earlier *in vitro* experiments using  $\lambda$  *gal* DNA as template it was found that cyclic AMP and CRP stimulated *gal* mRNA synthesis  $5$ – $10$ -fold<sup>16</sup>. *gal* mRNA was measured by DNA-RNA hybridisation and the majority of the RNA molecules which were analysed were of large size. We have shown here that initiation of *gal* transcription at S2 is in fact more efficient than at S1, but that even with elevated NTP concentrations RNA polymerase terminates transcription prematurely. Thus the low amounts of hybridisable *gal* mRNA found *in vitro* in the absence of cyclic AMP and CRP were probably due to a defect in elongation and not of initiation of transcription. Hence the high levels of *gal* expression which are observed *in vivo* in the absence of cyclic AMP or CRP could be due to a mechanism which would prevent premature termination of transcription. We propose that repression of *gal* transcription from S2, as is observed *in vivo*, could control the rate of premature termination.

We thank Sankar Adhya, Max Gottesman, Asis Das and Susan Gottesman for helpful discussions, Bruno Bruni for the *recA* derivative of MR93, and Ray Steinberg for help with the illustrations.

# Structure and control of phosphofructokinase from *Bacillus stearothermophilus*

P. R. Evans & P. J. Hudson\*

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

*The allosteric enzyme phosphofructokinase binds its substrate fructose-6-phosphate between two subunits of the tetramer, and allosteric effectors between another pair of subunits. The effector binding site accommodates both the activator and the inhibitor. The substrate cooperativity and allosteric control are mediated by these ligand bridges between subunits.*

PHOSPHOFRUCTOKINASE (EC 2.7.1.11) catalyses the phosphorylation of fructose-6-phosphate (F6P) by ATP to form fructose-1,6-diphosphate in a reaction which controls the rate of glycolysis in the cell.

The enzyme has been isolated from a wide variety of sources (for reviews, see refs 1,2), and its activity is regulated by a variety of intracellular metabolites, depending on the source. The enzymes from muscle and from yeast have complex oligomeric structures with subunits of molecular weight 85,000 (refs 1,2) and 100,000 (ref. 3) respectively. In contrast, the enzymes from bacteria are much smaller, and have simpler control properties.

We have worked on the phosphofructokinase (PFK) from the thermophilic bacterium *Bacillus stearothermophilus*, which is a stable tetramer of identical subunits each of molecular weight 33,900. The complete amino acid sequence of 316 residues has been determined<sup>4</sup>. Preliminary kinetic analysis shows a sigmoidal dependence of activity on the concentration of the substrate F6P, allosteric activation by ADP, and inhibition by phosphoenolpyruvate (PEP) (H. Hengartner, unpublished). This allosteric behaviour is similar to that found for the enzyme from *Escherichia coli*, which has been explained with two states of the molecule, an active R-state and a less active T-state<sup>5</sup>. Both enzymes behave as K-systems, that is the two states differ in their affinity for the cooperative substrate F6P, but not in their catalytic rate  $k_{\text{cat}}$ . Unlike the eukaryotic PFKs, these bacterial

enzymes are not inhibited by ATP or citrate, nor activated by AMP. The relationship between the enzymes from prokaryotic and eukaryotic sources remains unclear. We have been looking for a stereochemical explanation of the enzyme activity and investigating the cooperativity of binding of F6P and the influence of the allosteric effectors on the activity. We present here a preliminary report on the structure and substrate binding to the enzyme, which suggests explanations for some of these phenomena.

## X-ray structure determination

PFK was purified from cell extracts of *B. stearothermophilus* by affinity chromatography on AMP-Sepharose<sup>6</sup> and ATP-agarose<sup>7</sup>. Large crystals suitable for X-ray diffraction were grown from ~2 M potassium phosphate pH 7.3 containing 2 mM fructose-6-phosphate, 1 mM dithiothreitol and 0.5 mM EDTA. X-ray photographs show that the crystals belong to space group I222 with cell dimensions 122.5 Å, 84.1 Å, 61.5 Å and with one subunit in the asymmetric unit. Native crystals were prepared for data collection by washing out the F6P with 2.5 M phosphate solution. Intensity data were collected to 2.4 Å resolution on a rotation camera for the native and three heavy atom derivatives, (*p*-hydroxymercuribenzoate, ethylmercury thiosalicylate, and Au(CN)<sub>2</sub><sup>-</sup>). An electron density map was calculated by the usual method of isomorphous replacement using phases calculated from the three heavy atom derivatives.

A phase improvement method suggested by Agarwal and Isaacs<sup>8</sup> was tried, starting with the isomorphous replacement map. A model structure was created by distributing atoms of atomic number 7 through the high density regions of the map, such that the number of atoms in the asymmetric unit was approximately correct (~2,400) and they were not too close together. The positions and thermal parameters for these dummy atoms were refined by a diagonal least-squares procedure<sup>9,10</sup>, and the calculated structure factors after eight cycles of refinement ( $R = 0.255$ ) were used to calculate phases. The calculated phase probability distributions were combined with those from the isomorphous derivatives<sup>11–13</sup>, and a second electron density map was calculated with these combined phases. Although the theoretical justification for this method is dubious, particularly at a resolution as low as 2.4 Å where the ratio of observations to parameters is only about 1.35, it does seem to sharpen the electron density in a useful way.

The two electron density maps were contoured on to small

\*Present address: Howard Florey Institute of Experimental Physiology and Medicine, University of Melbourne, Parkville, Victoria 3152, Australia.

**Fig. 1** *a*, Schematic drawing of the polypeptide chain of one subunit, viewed along the *x* axis. Arrows represent  $\beta$ -sheet strands (A-K) and cylinders represent  $\alpha$ -helices (1-13). *b*, Schematic drawing of the tetramer of PFK. Each subunit is shown divided into two domains, numbered 1 and 2. The four subunits are related by three orthogonal dyad axes (222 symmetry), which coincide with the crystallographic symmetry axes. There is a solvent filled hole of  $\sim 7$  Å diameter through the centre of the tetramer along the *y* axis, indicated by a cylinder. The positions of some of the sites A, B and C are marked, showing that sites A and C lie between subunits.

scale map stacks ( $1 \text{ Å} = 2.5 \text{ mm}$ ). From these we could trace the course of the entire polypeptide chain, and locate nearly all the amino acid side chains. It was easier to trace the main chain through the map from the combined phases, but more recent model building into the density on a computer graphics system<sup>14</sup> has shown that the shape of the electron density is better in the isomorphous map. Nevertheless, the procedure was useful in aiding the initial interpretation and improving some of the poorer regions of the density. Part of the isomorphous replacement map is shown in Fig. 2, showing the top of domain 1 and the central  $\beta$ -sheet of domain 2. The interpretation of nearly all of this map was clear, particularly in the helices and the  $\beta$ -sheet regions. The positions and shapes of the side chains agreed with the chemical sequence, aromatic residues and methionines being unmistakable. In the internal parts of the structure, most of the main chain carbonyl groups could be seen as bulges on the electron density. A few of the loops on the surface were less clear, particularly the loops between helix 1 and sheet strand B, and between helices 3 and 4. Details of the crystallography will be published elsewhere.

### The structure of the protein

This description is based on the approximate  $\alpha$ -carbon coordinates measured from small-scale map at 2.4 Å resolution. The more precise model building into the electron density confirms

all the essential features. Figure 1*a* illustrates one subunit, and Fig. 3 shows the  $\alpha$ -carbon chain in stereo with the subunit interactions, the substrates and effectors. Figures 4 and 5 are also schematic views of two halves of the tetramer.

The PFK subunit consists of two domains each of which has a central  $\beta$ -sheet sandwiched between  $\alpha$ -helices, a type of fold which has been seen in a number of proteins ( $\alpha/\beta$  class of proteins of Levitt and Chothia<sup>15</sup>). However, the topology of the  $\beta$ -sheet strand connections in both domains of PFK is different from that in any other known protein structure. The first domain (Fig. 1*a*) has seven strands of  $\beta$ -sheet, the central five being parallel, and the outer two antiparallel to the others. The second domain has four parallel strands. The two sheets point towards a deep cleft which forms the active site (see below). Starting from the amino terminus, the chain first forms the main part of domain 1, including five strands of sheet A to E, and helices 1-5, then crosses to the second domain through the long helix 6. There follows most of domain 2, then the chain returns to domain 1 for the last two sheet strands J and K. Finally an extended chain returns to domain 2 for the final helix 13. Domain 1 consists approximately of residues 1-131 and 251-301, and domain 2 of residues 132-250 and 302-316. This insertion of one domain into the middle of the polypeptide chain of another is unusual in domain proteins: in most cases the domains are segregated along the chain, although the final crossing to the other domain for a C-terminal helix is more common (for example, glyceraldehyde-3-phosphate dehydrogenase<sup>16,17</sup> and phosphoglycerate kinase<sup>18</sup>). Other proteins with such inserted domains include pyruvate kinase<sup>19</sup> and the *E. coli* arabinose-binding protein<sup>20</sup>. All but one of the connections between successive parallel  $\beta$ -strands are right-handed<sup>21,22</sup>: the exception is the connection between strands E and J, where the connecting loop contains the whole of the second domain, about 157 residues.

Each subunit forms close contacts with only two of the other subunits in the tetramer. The interaction across the dyad along *z* is shown in Figs 3*a* and 4: the end of helix 6 is tightly packed against the neighbouring subunit, and the  $\beta$ -strands I interact across the dyad axis. The relative twist of these strands is in the wrong direction for extensive antiparallel  $\beta$ -sheet interactions, but two hydrogen bonds are formed across the dyad axis. The other subunit contact, across the dyad along *x*, is shown in Figs 3*b* and 5. The main interaction is the packing between the three helices 1, 3 and 11, and three helices 6, 7 and 13 in the other subunit. Also the bend between the  $\beta$ -strands J and K is in contact with its counterpart across the dyad. Figure 3*c* is a view of the tetramer from the end of the subunits, along *y*, and shows both of these subunit contacts. A solvent-filled hole  $\sim 7$  Å in diameter passes through the middle of the tetramer separating the pairs of subunits which do not interact.

**Table 1** Compounds binding to the three binding sites A, B and C

A	Active site	Effector site
	B	C
F6P	ADP/Mg or Mn	$P_i$
$P_i$	AMPPNP/Mg or Mn	ADP/Mg or Mn (activator)
(FDP)	(ATP)	PEP (inhibitor)

Compounds in brackets have not been observed, but are assumed to bind in these sites. Binding of ligands other than  $P_i$  in site C is only observed in crystals which have been transferred to 1.25 M sodium citrate (pH 7.3), or to 2.5 M potassium tartrate (pH 7.7). In the citrate solutions, and tartrate solutions containing ADP, the phosphate ion in site C is displaced, but the phosphate in site A remains. Transfer of the crystals to tartrate solution in the absence of other ligands causes the crystals to crack and change their space group, suggesting that a structural change has occurred. No binding of tartrate or citrate ions is apparent.

**Fig. 2** Sections  $z = 20/76$  to  $26/76$  of the isomorphous replacement electron density map. This view corresponds to those in Figs 3a and 4. The grid lines are at intervals of  $10 \text{ \AA}$ . One subunit is outlined: part of the subunit related by the dyad axis marked on the  $z$  axis is shown at the top. Outlines of the difference electron density for F6P and ADP are shown. The F6P outline encloses the high density peak representing the inorganic phosphate ion in the native map (labelled P). The ADP outline is labelled A for adenine, R for ribose, P for the  $\alpha$ -phosphate, and Mg for the magnesium ion. Three of the side-chains which bind the F6P molecule are indicated: His 246 and Arg 159 (from the upper subunit) bind the phosphate together with Arg 240, which is above the sections shown. Met 166 is one of the residues forming the pocket for the fructose ring. The four  $\beta$ -sheet strands of domain 2 are labelled F, G, H, I, and three  $\alpha$ -helices are labelled 4, 5 and 8 (compare Fig. 4).

## Binding studies

The binding of several compounds has been studied in the crystal, mostly using data to  $6 \text{ \AA}$  resolution, but with one set of data to  $2.4 \text{ \AA}$  resolution. There are three binding sites per subunit, sites A and B forming the active site and site C which appears to be the effector site. The molecules which bind to these sites are summarised in Table 1. Site A binds F6P in the crystals as grown, but this is replaced by  $\text{PO}_4^{3-}$  when F6P is washed out to make the native crystals. The phosphate ion is the highest peak in our electron density map (Fig. 2). Presumably this site should also bind fructose-1,6-diphosphate (FDP), but crystals soaked in this compound show only weak binding. Site B binds ADP with either  $\text{Mg}^{2+}$  or  $\text{Mn}^{2+}$ , but difference maps from crystals soaked in ATP show density identical to ADP, perhaps because of hydrolysis of ATP by the enzyme. The ATP analogue AMPPNP (5'-adenylylimidodiphosphate) binds in this site also with either  $\text{Mg}^{2+}$  or  $\text{Mn}^{2+}$ , and shows additional electron density which presumably represents the  $\gamma$ -phosphate group. Site C appears to be the effector site, and binds a phosphate ion in our native crystals: this ion also shows clearly in the electron density map. This site binds both the activator ADP and the inhibitor PEP.

## Details of the binding sites

Figures 4 and 5 show the binding of the substrate pair F6P and ATP/Mg in the active site, and the activator ADP/Mg in the effector site. These are superimposed on diagrams of two subunits from the tetramer, together with those side chains which are in contact with the ligands. The positions of the bound molecules were taken from a difference map at  $2.4 \text{ \AA}$  resolution from crystals soaked in F6P, ADP and Mg in  $2.5 \text{ M}$  potassium tartrate. This map showed clear density for F6P in site A and ADP/Mg in the effector site C, but the ADP/Mg in site B was less clear and only about half occupied: there was no electron density for the  $\beta$ -phosphate. Models of the three ligands were fitted to the electron density on a small Richards' box. The drawings show ATP in the active site, based on the  $2.4 \text{ \AA}$  resolution ADP density and the  $\gamma$ -phosphate position from a difference map between AMPPNP and ADP at  $6 \text{ \AA}$  resolution. The magnesium ions are clear in the difference electron density and correspond to their positions deduced from the  $6 \text{ \AA}$  resolution difference map between  $\text{Mn}^{2+}$  and  $\text{Mg}^{2+}$ .

**Site A.** The notable feature of this site is that the 6-phosphate group of F6P (and the phosphate ion in the native crystals) is

bound by amino acid side chains from two adjacent subunits, His 246 from one subunit, and Arg 159 and Arg 240 from the other subunit (Fig. 4). Thus the cooperative ligand F6P bridges between two subunits. The 1-hydroxyl is close to the  $\gamma$ -phosphate of ATP, and appears to be hydrogen bonded to Asp 124. This residue may act as a base catalyst for the reaction by increasing the nucleophilicity of the  $1\text{-OH}$  group. This phosphorylation site lies in the boundary between the two domains of the subunit, while the groups which bind the sugar ring of F6P (Arg 249, Met 166, Glu 219 and Asp 124) come from domain 2 of the subunit (the right-hand domain in the lower subunit in Fig. 4).

**Site B.** The conformation of ADP (and hence ATP) in this site is not very clear from our current maps, nor are all the interactions with side chains. The magnesium ion binds in the same position with both ADP and AMPPNP (and therefore presumably with ATP). In ADP it binds to the  $\alpha$ -phosphate and possibly to the invisible  $\beta$ -phosphate: in ATP it probably bridges the  $\alpha$ - and  $\beta$ -phosphate groups. The ATP molecule is bound to domain 1 with the  $\gamma$ -phosphate near the domain boundary: the only residue involved from domain 2 is Arg 168, which becomes ordered near the phosphates when the nucleotide is bound. Asp 100 may be involved in the binding of  $\text{Mg}^{2+}$ .

**Site C.** While the substrate F6P is bound between the subunits related by the  $z$  dyad axis, the effector is bound in a cleft between subunits related by the  $x$  dyad. The key interaction with ADP seems to be with the  $\beta$ -phosphate group, which replaces the phosphate ion bound to this site in the native crystals. This phosphate is bound by three arginine residues, Arg 151 from the upper subunit in Fig. 5, and Arg 21 and Arg 25 from the lower subunit. The ribose is bound by His 212 and Thr 155. The  $\text{Mg}^{2+}$  ion bridges the  $\alpha$ - and  $\beta$ -phosphates of ADP, but its only interaction with the protein seems to be with a main chain carbonyl group. The diphosphate of ADP points into a cleft, which is consistent with the specificity of the site for ADP rather than AMP or ATP, and its lack of specificity for the base<sup>5</sup>. The phosphate group of PEP appears to bind in the same place as the  $\beta$ -phosphate of ADP. This site is best considered as a phosphate binding site, rather than a nucleotide binding site.

## Discussion

This structure of *B. stearothermophilus* PFK seems to correspond to the active R-state of the Monod, Wyman, Changeux model<sup>5,23</sup>. A structural change caused by transferring the crystals to tartrate solution suggests that a second conformational state exists. All the structures we have been able to look at contain either phosphate ion or F6P bound in site A, and we

**Fig. 3** Orthogonal stereo views of the  $\alpha$ -carbon atoms of PFK together with the substrates F6P and ATP/Mg, and the activator ADP/Mg, viewed towards the centre of the tetramer. *a*, The upper two subunits of the tetramer viewed along the *z* axis (compare Fig. 4). *b*, The upper two subunits viewed along the *x* axis (compare Fig. 5). *c*, The upper half of the tetramer viewed along the *y* axis. Only half of each subunit is shown. The three ligand binding sites are indicated.

suggest that the removal of these ligands triggers the structural change to the less active T-state. Without knowing its structure, we cannot account in detail for the difference in affinity for ligands between the two states, but the nature of the binding site suggests a plausible explanation. The F6P site bridges two subunits, so a change of the relative position of these subunits could remove the two arginines 159 and 240 from the F6P site, reducing its affinity for F6P without changing the mode of binding. As the active site of PFK lies between the two domains of the structure, it would seem likely that any relative movement of these domains would change the catalytic rate,  $k_{cat}$ , by moving

the catalytic groups. As a change of  $k_{cat}$  is not observed, a more plausible model for the allosteric transition is a rearrangement of essentially rigid subunits into a different quaternary structure. This would contrast with other enzymes in which two domains within a subunit move on binding of substrates: these include hexokinase<sup>24</sup>, glyceraldehyde-3-phosphate dehydrogenase (A. J. Wonacott, personal communication) and probably phosphoglycerate kinase<sup>18</sup>.

The effector site lies at the interface between another pair of subunits; as it binds both activator and inhibitor, the affinity for these molecules must change in opposite senses during the

**Fig. 4** Schematic view of the two subunits along the *z* axis towards the centre of the tetramer. The substrates and activator are shown, and the side chains around the active site and effector site.

allosteric transition. The local changes around this site are different with binding of ADP and of PEP, but we cannot explain the relative affinities of the two conformations without knowing the structure of the T-state.

Each subunit in the tetramer has an interface with two other subunits, one of these is bridged by F6P, the other by the effector (see Fig. 3c): thus catalysis and control require the whole tetramer. Figure 4 shows that the active site is close to the effector site, and the part of the enzyme that lies between the sites, particularly residues 151 to 159, has side chains pointing in one direction to the F6P site and in the opposite direction to the effector site. Thus binding of a ligand in either site could affect

directly the ligand affinity in the other site, in addition to the indirect effect caused by shifting of the equilibrium between the two conformational states.

All three binding sites in PFK bind phosphate groups, but there are interesting differences between them. Sites A and C both bind an inorganic phosphate ion as well as their specific ligands, and they have a clear electrostatic mode of binding: site C binds the phosphate with three arginine residues, and Site A with two arginines and a histidine. In contrast, site B does not bind inorganic phosphate, and does not have such a clear positively charged nature, although arginine 168 is close and the  $Mg^{2+}$  ion is bound to the  $\alpha$ - and  $\beta$ -phosphates of ADP and ATP. The phosphates in this site are at the amino end of helix 5, and it has been suggested that the dipole of an  $\alpha$ -helix provides approximately half a positive charge at its amino end<sup>25</sup>. The difference between the three sites may be related to the requirements for binding at sites A and C, compared to binding and catalysis at site B. Site C is unusual in that it lies at the amino end of a  $\beta$ -sheet. In most proteins with parallel  $\beta$ -sheets, the binding sites for all types of ligand are at the carboxy end of the sheet (although the secondary ADP site in pyruvate kinase is at the amino end of the  $\beta$ -sheet barrel<sup>19</sup>). However, this effector site C is required by its function to be in the subunit interface, and this requirement presumably outweighs other preferences.

Over the past few years, there has been much discussion about the similarities between the tertiary structures of some proteins and whether these relationships are due to the rules of polypeptide folding or to evolutionary homology<sup>26-29</sup>. Among proteins with central  $\beta$ -sheets ( $\alpha/\beta$  proteins), four different dehydrogenases resemble each other in one of their two domains. In contrast, five different kinases (adenylate kinase<sup>30</sup>, hexokinase<sup>31</sup>, phosphoglycerate kinase<sup>18,32-34</sup>, pyruvate kinase<sup>19</sup> and PFK) show much less similarity. Although they all contain domains built around parallel  $\beta$ -sheet, the topological arrangement of these sheets are different, and their mode of binding substrates is different. These differences suggest that these kinases do not share a common ancestor.

## SS433—a massive black hole?

THE peculiar emission line object SS433 has recently been the subject of interest following new spectrophotometric observations by Margon *et al.*<sup>1</sup>, and previous suggestions identifying it with the supernova remnant (SNR) W50 (ref. 2) and also with the X-ray source A1909+04 (ref. 3). Margon *et al.*<sup>1</sup> report "three very strong (equivalent widths 50–150 Å) broad emission features in the green, red and IR, which change in intensity, profile and wavelength daily." In this note we propose that the reported red and IR lines (at  $\sim 6,000$  Å and  $\sim 7,400$  Å, respectively) are Doppler-shifted H $\alpha$  lines which are emitted from a ring of matter orbiting around a  $\sim 10^6 M_\odot$  black hole. (The green line at  $\sim 5,200$  Å may be the redshifted H $\beta$  line.) The ring itself may be part of an accretion disk and its radius is  $\sim 20$ – $25$  gravitational radii ( $R_g = 2GM/c^2$ ). The intensity of an emission line per observed Doppler-shifted frequency interval in such a ring is maximal at the two extreme ends of the spectrum<sup>4</sup>, in any case of emission constant along the ring. These maxima are quite sharp; in the non-relativistic case, we have

$$dI_\nu/d\nu \propto \{\nu_0^2 - (\partial\nu)^2\}^{-1/2}$$

where  $\partial\nu$  is the frequency shift and  $\nu_0$  depends on the radius of the ring and on its inclination with respect to us. Also, due to the gravitational redshift in our case, the centre-of-mass of the red and IR lines emitted from such ring is additionally redshifted.

It is difficult to determine the relative intensity of the Doppler-pair members observationally, because of the uncertainty in the reddening out to SS433; if one takes  $A_V \sim 7$  mag, as is reasonable for a distance of  $\sim 3.3$  kpc in the galactic plane, the data of Margon *et al.* are consistent with both members having roughly equal intensities or even having the blueshifted member slightly stronger, as expected for such a model<sup>4</sup>. Also, to match these observed shifts<sup>1</sup>, the plane of the ring should be inclined towards us<sup>4</sup>. Our numerical calculations for a model line emitted from such a ring are consistent with the structure of the observed pair in Fig. 3 of ref. 1 for inclination angles of  $45$ – $60^\circ$ .

Accumulated results of observations (J. Katz, personal communication) of the above and other shifted lines from SS433 show the following characteristics:

- (1) Let  $B = (\lambda_{\text{blueshifted}} - \lambda_0)/\lambda_0$ ,  $R = (\lambda_{\text{redshifted}} - \lambda_0)/\lambda_0$  and let  $c$  be the velocity of light. then,  $\frac{1}{2}c(R+B)$  has now varied between  $\sim 10,000$  km s<sup>-1</sup> and  $\sim 40,000$  km s<sup>-1</sup>. These high velocities strongly point to processes in a region of high gravitational field, near a neutron star or black hole.
- (2) During these variations of  $B$  and  $R$ , the centre-of-mass (COM) of the lines ( $\frac{1}{2}c(R+B)$ ) remains fairly constant<sup>5</sup>, redshifted at  $\sim 10,000$  km s<sup>-1</sup>. This poses severe difficulties on models in which the changes in  $R$  and  $B$  are due to velocity magnitude changes alone (rather than to changes in angle, such as a precession of the ring<sup>6</sup>, say, which is suggested by a possible periodicity in the data<sup>5,7</sup>). It also indicates that the emission region for the shifted lines remains at a fairly constant gravitational redshift (that is, distance from the compact object).
- (3) The shifted lines are accompanied by an unshifted line. This poses a difficulty on any interpretation of the shifted COM as an overall motion of SS433.
- (4) The shifted lines are quite narrow,  $(\delta\lambda/\lambda)/B_{\text{max}} \leq 10\%$ , suggesting a reasonably narrow emission region.

(5) Let the line-emitting region be of surface area  $4\pi R^2$ . Then its brightness temperature  $T_b$  must satisfy  $T_b > 10^9$  K  $(R/10^9 \text{ cm})^{-2}$ . This poses severe difficulties on neutron star models and on models having black holes with  $R_g \leq 10^{11}$  cm ( $M \leq 3 \times 10^5 M_\odot$ ), particularly with no observational evidence for coherent emission.

(6) In several of the H $\alpha$  Doppler-shifted pairs<sup>1</sup>, one line seems to be the mirror image of the other (imaging on the  $\lambda$  axis, mirror located at the COM). This indicates a correlation between the geometries of the two emission regions, such as that found in emission from a ring. In pairs observed at other times, no such symmetry was found (J. S. Gallagher, personal communication), suggesting that the emission region has variable structure, or that its appearance to us is variable.

We infer from these considerations that the compact object, around which the emission takes place, cannot be a neutron star or a light black hole, but rather the above mentioned  $\sim 10^6 M_\odot$  black hole. An optically thick accretion disk around such a black hole has indeed most of its flux coming from such ring, at UV and visible frequencies<sup>8</sup>. Note, that if the centre of the SNR W50 is at distance  $\geq 10$  pc from SS433 (ref. 1), the disk may be fed by the SNR (although interstellar matter, if its density near the black hole is close to its average value in the Galaxy, can do the same); for typical values<sup>9</sup> of the particle density ( $\sim 1$  cm<sup>-3</sup>) and velocity ( $\sim 100$  km s<sup>-1</sup>) in such SNR, the feeding is at a rate of  $\leq 10^{-7} M_\odot$  per yr, giving a total luminosity of  $\leq 10^{39}$  erg s<sup>-1</sup> if the disk is in steady state. This is consistent with the observed optical luminosity, which seems to indicate that  $M_v \leq -3.5$  (ref. 1).

The unshifted H $\alpha$  line<sup>1</sup> could arise from reprocessing of some of the  $\leq 10^{39}$  erg s<sup>-1</sup> optical and UV radiation from the black hole, in the rim of the disk<sup>10,11</sup>. This suggests that SS433 might be a strong UV source and that the shifted lines may also be due to reprocessed UV radiation.

Our model also suggests that the whole system may be part of an old globular cluster.

We thank Jonathan Katz for stimulating discussions. T.P. thanks the Racah Institute for hospitality and the NSF (grant PHY77-22489) and SRC for support.

## Hard X-ray spectrum of Cyg X-1

THE three most likely black hole candidates known in X-ray astronomy are Cyg X-1, Circ X-1 and V 861 Scorpii<sup>1</sup>. Cyg X-1 has a key role as it is the best studied of these objects. Unfortunately, the evidence for its being a black hole is entirely circumstantial; namely, the mass of the compact object and its observed short time variability. The spectrum of Cyg X-1 is also very different from those of accreting neutron stars, but it is similar to spectra of extragalactic sources which may contain massive black holes. Eardley *et al.*<sup>2</sup> have recently reviewed the existing evidence. Here we consider only the X-ray spectrum and the source luminosity. This work was motivated by the spectral measurements with very high statistical accuracy of Cyg X-1 made in the hard X-ray range by the AIT/MPI group<sup>3</sup>. Progress has been made in Moscow in calculating source spectra expected from hot accretion disks. Thus, there is a new basis for a comparison between observational results and theoretical predictions.

Measurements by numerous rocket, satellite and balloon experiments have shown that the Cyg X-1 spectrum is variable on different time scales (see ref. 4). In particular, the source exhibits 'flares' and transitions between high and low spectral states<sup>5,6</sup>. Matteson *et al.*<sup>7</sup> stressed that despite this variability most of the observed spectra lie near a 'normal' spectrum which can be characterised by a power law.

$$\frac{dN}{dE} = 3 \times 10^{-2} \left( \frac{E}{10 \text{ keV}} \right)^{-1.6} \quad (\text{photons cm}^{-2} \text{ s}^{-1} \text{ keV}^{-1}) \quad (1)$$

for  $2 \text{ keV} \leq E \leq E_b$ , while beyond  $E_b$  the spectrum steepens significantly. A range of values has been quoted for this break energy:  $E_b = 32 \text{ keV}$  (ref. 8),  $85 \text{ keV}$  (ref. 7),  $115 \text{ keV}$  (ref. 9) and  $\geq 150 \text{ keV}$  (ref. 10). During the past 10 yr the source has apparently spent most of its time ( $\sim 90\%$ ) in this normal spectral state which has also been called the 'low' or 'non-flaring' state. The 'high' state in which the source is seen temporarily<sup>5</sup> is characterised by a steep spectrum in the 2–10 keV range. As far as the break energy of the normal spectrum is concerned, it is not clear to what extent the quoted differences are due to the difficulty in positioning a 'spectral break' in the presence of statistical and systematic errors. On the other hand, the break energy is a very important parameter, as in the current comptonisation models it is related to the electron temperature of the scattering electrons (see ref. 2).

The hard X-ray spectrum of Cyg X-1 has been measured with high accuracy by the balloon group of the Astronomisches Institut Tübingen and MPI Garching on three different flights: 20 February 1975; 2 May 1976 and 20 September 1977. These measurements cover the spectral range from 15 to 150 keV. Figure 1 shows the data obtained on 20 September 1977 which have unprecedented accuracy.

The spectra taken during these three flights agree with each other to within  $\sim 30\%$  and lie very close to the normal spectrum quoted above. They all show a steepening below 100 keV (ref. 3). Furthermore, they agree both in spectral slope and absolute intensities (within  $\sim 40\%$ ) with high quality rocket spectra taken by the GSFC group on 4 October 1975<sup>11</sup>. All these data suggest that the normal state has a more definite intensity (to  $\leq 40\%$ ) than previously assumed.

The X-ray emission of Cyg X-1 has been explained in terms of disk accretion on to a black hole<sup>12–14</sup> which is determined by the following parameters<sup>13</sup>: (1) the mass of the black hole  $m = M_x/M_\odot$ ; (2) the accretion rate  $\dot{m} = \dot{M}/\dot{M}_{\text{edd}}$  where  $\dot{M}_{\text{edd}}$  is the Eddington critical accretion rate; (3) the turbulence parameter  $\alpha$ .

At small accretion rates ( $\dot{m} \ll 1$ ) the disk is stable but cool and unable to produce the observed hard X-ray spectrum. If the

accretion rate (onto a Schwarzschild black hole) becomes

$$\dot{m} \geq \frac{1}{50} (\alpha m)^{-1/8} \quad (2)$$

the radiation pressure will exceed the gas pressure in the inner part of the disk<sup>13</sup> which leads to both secular<sup>15</sup> and thermal<sup>16,17</sup> instabilities. The unstable inner regions consist of hot and cold zones in pressure equilibrium. This means that the cold zones are dense and the production of low energy photons by bremsstrahlung and other collisional mechanisms is very effective. At the same time, these mechanisms are rather ineffective in the hot zones and hard X rays are mainly produced by comptonisation of the soft photons in the hot zone of the disk. This comptonisation is also the main cooling mechanism for the hot plasma.

As far as the physical nature and the detailed configuration of the hot gas component is concerned, various models have been discussed: a hot inner disk surrounded by a cooler disk<sup>18,19</sup>, instability driven random outbursts of hot gas<sup>16</sup>, a hot corona surrounding a cool disk<sup>20–22</sup>. The comptonisation of low energy photons in the high temperature electron clouds leads to the formation of power law X-ray spectra

$$J(\nu) \sim \nu^{-n} \quad \text{for } h\nu < kT_e \quad (3)$$

while above  $kT_e$  the spectrum cuts off roughly exponentially.

This was first shown in numerical calculations by Katz<sup>23</sup> for a non-relativistic plasma and by Pozdnyakov *et al.*<sup>24</sup> for relativistic and semi-relativistic plasmas using Monte Carlo methods. Shapiro *et al.*<sup>25</sup> found an approximate analytical formula for the spectral index of the power law spectrum.

Recently, Sunyaev and Titarchuk<sup>26</sup> derived an analytical solution for the comptonisation spectrum from a spherical, isothermal cloud in which a source of soft photons is embedded. This solution is valid for any spectral shape if the injected soft photons have an energy  $h\nu_{\text{soft}} \ll kT_e$ . The resulting high energy spectrum only weakly depends on the geometry of the clouds. For sufficiently high energies ( $h\nu \gg kT_{\text{soft}}$ ), the analytical solution for the comptonisation spectrum can be written using the integral representation of a Whittaker function

$$J(E) = Ax^3 e^{-x} \int_0^\infty t^{n-1} e^{\left(1 + \frac{t}{x}\right)^{n+3}} dt \quad (4)$$

where  $A$  is a constant and

$$\left. \begin{aligned} x &= \frac{E}{kT_e} = \frac{h\nu}{kT_e} \\ n &= -\frac{3}{2} + \left(\frac{9}{4} + \gamma\right)^{1/2} \\ \gamma &= \frac{\pi^2}{3} \frac{m_e c^2}{kT_e(\tau_0 + \frac{2}{3})^2} \end{aligned} \right\} \quad (5)$$

$\tau_0$  is the Thomson optical thickness of the electron cloud. In the low frequency limit  $x \ll 1$ , one easily obtains from the integral representation of the Whittaker function that the spectrum is a power law (the same as obtained by Shapiro *et al.*<sup>25</sup>):

$$J(E) \sim x^{-n} \quad (6)$$

Likewise in the high frequency limit  $x \gg 1$  the spectrum is of the Wien-type

$$J(E) \sim x^3 e^{-x} \quad (7)$$

A fit of the spectrum given by equation (4) to the observed low state spectrum (Fig. 1) yields the following set of parameters:

$$\begin{aligned} kT_e &= 27 \text{ keV} \\ \tau_0 &= 5 \end{aligned} \quad (8)$$

Figure 1 shows the theoretical curve which is an excellent fit to

**Fig. 1** Low state spectrum of Cyg X-1, observed on 20 September 1977 by the MPI/AIT balloon experiment<sup>3</sup>. The solid curve represents a photon spectrum expected by comptonisation of soft photons in an electron cloud with a temperature of  $2.5 \times 10^8$  K and a Thomson optical thickness  $\tau_0 = 5$ .

the experimental data. Note that the temperature ( $T_e \sim 3 \times 10^8$  K) is much less than that obtained in previous papers<sup>2,25</sup> ( $T \sim 10^9$  K).

We conclude that the comptonisation of soft photons by a hot gas gives a very good description of the observed low state spectrum. As the hard X-ray band (30–100 keV) contains the main part of the overall luminosity, this radiation must come from the inner region of the disk where the main energy release occurs. This region is quite compact (see ref. 13) and the larger and cooler outer regions do not contribute appreciably to the low state flux.

An integration of the spectrum for  $E \geq 1$  keV yields

$$L_x = 2.3 \times 10^{37} \left( \frac{d}{2.5 \text{ kpc}} \right)^2 \text{ erg s}^{-1} \quad (9)$$

Thus, for a distance of 2.5 kpc (ref. 27) the observed luminosity is roughly 65 times below the Eddington critical luminosity for a  $10 M_\odot$  black hole which is given by

$$L_{\text{edd}} = 1.3 \times 10^{39} \left( \frac{M_x}{10 M_\odot} \right) \text{ erg s}^{-1} \quad (10)$$

Therefore, the accretion rate  $\dot{m}$  derived from observations is a factor  $\sim 1.3$  lower than that required to obtain an unstable disk according to equation (2).

Before discussing this result we shall summarise briefly the requirements on the soft X-ray source feeding the comptonisation process. According to Sunyaev and Titarchuk<sup>26</sup>

$$L_x = L_{\text{soft}} \left( 1 + 2.9 \frac{kT_e}{\langle h\nu_{\text{soft}} \rangle} \right)^{1-n} \quad (11)$$

which for  $L_x = 2.3 \times 10^{37} \text{ erg s}^{-1}$ ,  $kT_e = 27 \text{ keV}$  and  $n = 1.56$  yields

$$L_{\text{soft}} \approx 10^{36} \left( \frac{100 \text{ eV}}{\langle h\nu_{\text{soft}} \rangle} \right)^{0.44} \text{ erg s}^{-1} \quad (12)$$

What is the black-body temperature of the region where the main energy release occurs? For a Schwarzschild black hole this region has a radius of  $\sim 7$  gravitational radii ( $r \sim 2 \times 10^7 \text{ cm}$ ). The total luminosity of this region is given by  $2\pi r^2 \sigma T_{\text{soft}}^4$ . Equating this to  $L_{\text{soft}}$  as given by equation (12) and using

$$kT_{\text{soft}} = \frac{\langle h\nu_{\text{soft}} \rangle}{2.7}$$

we find

$$kT_{\text{soft}} \approx 100 \text{ eV} \quad (13)$$

The soft X-ray source must possess a luminosity of a few times  $10^{35} \text{ erg s}^{-1}$  and a temperature of the order of  $10^6 \text{ K}$ .

We now reconsider why the observed X-ray luminosity is not sufficient (by a factor 1.3) to make the disk unstable. Within this framework of the black hole disk accretion models there are two solutions: (1) the discrepancy of a factor of  $\sim 1.3$  is due to uncertainties in the observational and theoretical figures; and (2) there could be a large contribution to the radiation pressure due to unobservable (soft X and XUV) photons.

In the first case, the accretion disk must be quite close to the lower boundary (in  $L_x$ ) of the region of instability. This is true if Cyg X-1 is a  $10 M_\odot$  black hole, but also if it is a Kerr black hole for which the requirements on the mass accretion rate and total luminosity would be a little lower than given by condition (2). The marginal instability may lead to the total disappearance of the hard X-ray flux, if the mass accretion rate drops below the critical value. Although this critical mass accretion rate is not known precisely (it may be below the 'normal' rate by a factor of 2 to 3) it should represent a sharp threshold which is different for Schwarzschild and Kerr black holes. To our knowledge, there is no observational evidence for such 'off-states'. However, they might be very short (several seconds) if they are due to stochastic fluctuations of the accretion rate in the central parts of the disk. The detection of such short 'off-states' in the X-ray flux from Cyg X-1 and the other black hole candidates would be very important. In the long run, a precise determination of the threshold X-ray luminosity might yield information about the metric of the accreting black hole.

The other possibility is that the actual accretion rate and luminosity are considerably higher than the observed values, so that the disk is permanently unstable. This contribution to the overall luminosity must be substantial ( $\geq 2 \times 10^{37} \text{ erg s}^{-1}$ ) and should consist of soft X-ray and XUV photons. The corresponding sources may be the cool parts of the disk, however, the required luminosity is much larger than that given by equation (12). Therefore, this case requires that the bulk of the soft flux freely escapes from the disk while only a small part (a few per cent) is subjected to the comptonisation process. A condition for this is, of course, that the hot gas clouds cover only part of the disk. Such large 'soft' luminosity of the disk would require a higher temperature ( $kT_{\text{soft}} \sim 250 \text{ eV}$ ) than given by equation (13). Soft X-ray observations with high sensitivity may indicate a soft component in the low state spectra. Optical observations of the accretion disk would be important in this context as they may give information about the total energy flux which heats the peripheral parts of the disk<sup>28</sup>.

We thank Ya. B. Zeldovich and L. G. Titarchuk for stimulating discussions. J. T. thanks the Academy of Sciences of the USSR and the Deutsche Forschungsgemeinschaft for making a visit to Moscow possible.

## Search for short time-scale periodicity in the X-ray flux of 4U1700-37

THE first suggestion<sup>1,2</sup> of the existence of a  $\sim 24$  min periodicity in the X-ray light curve of 4U1700-37 was followed by the report<sup>3</sup> of the detection of a  $\sim 97$ -min period in the X-ray data from the SAS C satellite when pointing at the same source. We report here how a new recent Copernicus observation of 4U1700-37 was used to test the existence of a short-term modulation of the X-ray flux.

In July 1978 the Copernicus satellite observed 4U1700-37 for a complete binary cycle between day no. 191.2 and day no. 194.8 (from phase 0.48 of a cycle to phase 0.52 of the following, according to the ephemeris given in ref. 2) and again between day no. 195.7 and day no. 196.5 (phase 0.80-0.01). The data collecting time of the X-ray instrumentation<sup>4,5</sup> was 62.9 s every 86.5 s (23.6 s dead time). The X-ray data are shown in Fig. 1, integrated in bins of  $\sim 1$  h duration, after subtraction of the diffuse sky and particle background. A low amount of contamination ( $\sim 20$  counts per 62.9 s on average) from the nearby X-ray source Sco X-2 is present and visible during the 4U1700-37 eclipses. This would not affect the detection of a periodic modulation, if any, in the X-ray flux of 4U1700-37, but it does increase the noise in the search for periodicities.

For our analysis we used all the July 1978 Copernicus X-ray data relative to the non-eclipsed part of 4U1700-37 light curve. The data sampling interval of 86.5 s allowed the search

for periodicities down to  $\sim 3$  min (corresponding to the Nyquist frequency). Because of the Earth occultation and the regions of high particle background where the detector was switched off the data sets are not regularly spaced, so we used the technique of Gray and Desikachary<sup>6</sup> to Fourier analyse the data. We prewhitened the data of the low-frequency modulations by subtracting a low-order polynomial and we computed the periodograms of the residuals. No evidence of periodicity is present either in the range 20-30 min or 90-100 min, as well as over all the range down to  $\sim 3$  min. Most of the low-frequency noise is introduced in the periodograms by the intense X-ray flaring activity of 4U1700-37. This is the main problem to be overcome when searching for periodic modulation in the flux of a very variable source. We take the maximum value of the random noise peak-to-mean modulation as the upper limit to any true periodicity. Table 1 lists such upper limits for the ranges of period of interest and for increasing order of the polynomial

**Fig. 1** The X-ray light curve of 4U1700-37, after subtraction of the diffuse sky and particle background, as observed by Copernicus in July 1978. The crosses represent the  $1\sigma$  errors on the (3.1-9.4 keV) count-rate integrated in bins of  $\sim 1$  h duration. The contamination of Sco X-2 is low ( $\sim 20$  counts per 62.9 s on average) due to the favourable orientation of the detector's field of view (the efficiency at the location of Sco X-2 was  $\sim 20\%$ ). The times of phase 0.0 (centre of the X-ray eclipse) were calculated from the ephemeris given in ref. 2; the indicated length of the eclipse corresponds to the shortest ever observed (1975, Copernicus; ref. 2.). The gap in the data during day no. 195 is due to the observation of a different target.

fitted to the data. This was an attempt to decrease the low-frequency noise contribution to the periodograms so as to make a real, if any, periodicity show up. Table 1 shows that the technique is most useful to reduce the noise in the range of longer periods investigated. We have also searched for the suggested periodic behaviour in the 4U1700-37 X-ray light curve by folding the data modules' values in the ranges 23-25 and 96-98 min (at intervals of 0.1 min). The analysis is made difficult again by the intrinsic variability of the flux (the average peak-to-mean modulation is  $\sim 20\%$  at any value of the trial period, in agreement with the results of the Fourier analysis). No significant periodicity is evident above the noise.

The fact that the most recent X-ray observation of 4U1700-37 does not show evidence of any of the proposed periodicities can be interpreted in several ways.

(1) The true period is at  $\sim 24$  min, but it has already been shown<sup>2</sup> to be present at times and absent at others (possibly covered by the flaring activity of the X-ray source). It is, therefore, quite possible that it was again absent in the 1978 Copernicus observation. In this respect it is interesting that the mean X-ray flux of 4U1700-37 may have monotonically decreased during 1974-76 (see Table 2 in ref. 2). In the 1978 Copernicus data the X-ray flux is close to the value observed in 1975, also when no periodic modulation was detected.

**Table 1** Upper limits to the peak-to-mean amplitude of any periodic modulation in the ranges of period indicated

Order of the polynomial used to prewhiten the data	Ranges of period (min)	
	20–30	90–100
1	18%	50%
3	19%	17%
6	17%	19%

(2) If a periodicity at  $\sim 97$  min existed in March 1977<sup>3</sup> and was rotational in origin, it is possible that it could have disappeared in the 15 months which elapsed between the 1977 SAS C and the 1978 Copernicus observations (see the current theories of accretion torques on neutron stars in binary systems<sup>7,8</sup>). However, the rotation mechanism seems unlikely because of the very small probability of observing such a rapid changing period with the limited coverage of the satellites available for X-ray astronomy (the periodicity would only be present for a very short interval in the lifetime of the X-ray source). If a different origin for the proposed  $\sim 97$  min periodicity is invoked, then it is difficult to explain how such a strong modulation (up to 60% (ref. 3)) of the X-ray flux has escaped detection in all the other Copernicus observations of 4U1700–37 (one binary cycle in July 1974 (ref. 9), two cycles in July 1975 and August 1976 (ref. 2), one cycle in July 1978). In this context, it has been suggested<sup>10</sup> that the  $\sim 97$  min period in the SAS C data could be spurious, arising from the way the data were collected, namely gaps in the data (due to the satellite being in the South Atlantic Anomaly or Earth blocked, or to telemetry dropouts) with the overall shape of the data set.

(3) The 'transient' X-ray periodicities reported for 4U1700–37 could be due to occasional trains of quasi-periodic events in the flaring activity of the source. This variability may be interpreted as the result of shot noise; from the periodograms obtained by Fourier analysis of the Copernicus data we deduce a characteristic exponential decay time<sup>11</sup> of  $\sim 15$  min.

Much more observing time is required to satisfactorily clarify the temporal behaviour of 4U1700–37. In particular the data are too limited to precisely evaluate the third alternative proposed.

## X-ray observations of AM Herculis from OSO 8

THE white dwarf binary system AM Herculis (2A1815+500) has been observed in X rays at both low energies ( $E \leq 10$  keV)<sup>1–3</sup> and higher energies<sup>2,4,5</sup>. The exact shape of the spectrum, particularly at the higher energies, has yet to be determined. We present here results from the high energy scintillation spectrometer on OSO 8. These are combined with results published elsewhere<sup>6</sup> obtained concurrently with the proportional counter on the same satellite, thereby giving for the first time coincident observations of AM Her over the range 2–250 keV.

The OSO 8 instruments used to observe AM Her consist of a proportional counter<sup>7</sup> covering the photon energy range 2–40 keV, and a high energy scintillation spectrometer<sup>8</sup> covering the range 20–250 keV.

The source was observed during the period 1–10 October 1977. The results presented here from the scintillation spectrometer cover the whole period, whereas the proportional counter spectrum is based on 'quick-look' data taken during  $\sim 20\%$  of the period. The composite OSO 8 spectrum is shown in Fig. 1. Also shown for comparison are the spectrum of Staubert *et al.*<sup>5</sup> obtained on 20 September 1977, the Ariel 5 results<sup>4</sup> obtained during the period 18–22 February 1977 and the OSO 8 proportional counter spectrum obtained during the period 11–12 October 1975<sup>2</sup>. AM Her is an eclipsing binary system and all the results except those of Staubert *et al.*<sup>5</sup> have been averaged over the whole binary cycle. Since Staubert *et al.*<sup>5</sup> observed it for only part of a cycle, their results have been normalised by a factor of 0.83. This factor was obtained by comparing the phases of their observation periods with the 10–60 keV light curve of Swank *et al.*<sup>2</sup>.

Variations in the spectral shape and intensity are apparent in the results up to 100 keV. Even if the Ariel 5 results<sup>4</sup> in this energy range are not considered because of their low significance ( $\sim 1.7$  s.d.), there remains a statistically significant difference between the results of Staubert *et al.*<sup>5</sup> and OSO 8 taken only 10–20 d apart. If a thermal bremsstrahlung spectrum, including the modified Gaunt factor, is fitted to each data set, then apparent order of magnitude changes in temperature seem to be occurring (see, for example, the temperature of  $\leq 18$  keV found by Staubert *et al.*<sup>5</sup> to their 1977 observations and the temperature of 170 keV fitted by Swank *et al.*<sup>2</sup> to their 1975 OSO 8 data).

The X-ray emission of AM Her has already been shown<sup>9</sup> to vary in soft X rays ( $E \leq 10$  keV) by a factor of approximately four from one binary cycle to the next. The results summarised here indicate that changes in spectral shape also seem to be occurring. Although the changes in intensity are certainly real, the variations in temperature are not so well defined. The results from OSO 8 illustrate the confusion. In 1975 a single temperature fit to the data was found to be statistically unacceptable<sup>2</sup>, whereas in 1977 the opposite was true (Swank, personal communication). Furthermore, if the spectrum of Staubert *et al.*<sup>5</sup> is extrapolated to lower energies, then the flux in the 2–5 keV range would be at least one order of magnitude greater than that ever observed. Consequently, the latter results and the 1975 OSO 8 results suggest a spectral break being present, possibly at about 15 keV, on these occasions. The 1977 OSO 8 results, however, require no such feature.

If the spectrum of AM Her is definitely shown to possess a spectral break on some occasions, then at these times it will be similar to that seen from Her X-1 (ref. 10) in which a break is observed around 25 keV. The reason for the break in the Her X-1 spectrum is thought to be the modification of the Thomson cross-section in the intense ( $10^{13}$  G) magnetic field of the neutron star. The magnetic field of the white dwarf in AM Her is, however, believed to be of the order of  $10^8$  G from optical

**Fig. 1** Measurements of the X-ray spectrum of AM Her. The OSO 8 data below 50 keV come from the GSFC proportional counter experiment<sup>2,6</sup>, while the data above 50 keV come from the present work. The Ariel 5 data is from ref. 4, and the balloon data from Staubert *et al.*<sup>5</sup>. Upper limits are indicated at the two standard deviation level.

polarisation measurements<sup>12</sup>. The calculations of Canuto *et al.*<sup>11</sup> indicate that this would not be high enough to affect the X-ray photons. Consequently, if a break in the AM Her spectrum is subsequently confirmed, then some modified or alternative theory is required to explain it.

Finally, the upper limits obtained above 50 keV by Staubert *et al.*<sup>5</sup> and the present work make it unlikely that a  $\gamma$ -ray tail, such as that seen at the 3.2 standard deviation level in the Ariel 5 data<sup>4</sup>, existed on these occasions. In view of the possible spectral changes suggested by the results summarised in this work, however, the existence of such a feature on other occasions cannot be excluded.

We thank Dr Jean Swank for helpful discussions. The work of the OSO 8 Project Scientist, Dr Roger Thomas, and the personnel of COMTECH Incorporated is appreciated. M.J.C. is in receipt of an NAS/NRC Resident Research Associateship.

## Near IR surface brightness of southern galactic plane

NEAR IR surface of the Galaxy has been observed in balloon experiments<sup>1-6</sup>. The stellar distribution in the inner Galaxy thus obtained is related to the distributions of H I clouds, CO clouds,  $\gamma$  rays, OH-IR sources and so on<sup>7</sup>. These observations were restricted to the northern sky, and we have recently attempted to use balloon observations from Australia to study the overall structure of the Galaxy more completely. We found that (1) humps for 2.4- $\mu$ m surface brightness are asymmetric with respect to the galactic centre and attributed to the spiral structure; (2) the 2.4- $\mu$ m galactic plane is distorted from the flat plane in the regions around the most pronounced humps; (3) IR sources are highly concentrated in the plane to compensate interstellar absorption; and (4) the central region shows a complex structure.

The instrument we used is similar to that described by Ito *et al.*<sup>2</sup>. Incident radiation was focused by a 10-cm,  $F1.0$  silicon lens onto 11 PbS detectors, with fields of view of 0.5°, 0.8° and 1.7° at 2.4  $\mu$ m, and 2.0° at 3.4  $\mu$ m. The whole telescope system was cooled by liquid nitrogen to reduce the thermal background noise. The optical axis was fixed at an elevation angle of 40° and regularly scanned in azimuth through a 60° range centred on the galactic plane.

The payload was launched on 25 April 1978 at the Australian Balloon Launching Station, Mildura, Victoria, Australia. The instrument functioned satisfactorily during the whole flight, and the telescope surveyed the galactic plane between  $l = 290^\circ$  and  $20^\circ$ . During the azimuthal scans we observed several bright stars which enabled us to obtain the absolute flux value at 2.4  $\mu$ m within  $\pm 10\%$ , and to determine the latitude of the telescope within  $\pm 0.2^\circ$ . The absolute flux value at 3.4  $\mu$ m was obtained with lower accuracy.

The contour map obtained with the 1.7° field of view at 2.4  $\mu$ m is shown in Fig. 1, in which the contributions of bright stars,  $\alpha$ -Cen,  $\gamma$ -Cru, and  $\epsilon$ -Mus, are subtracted. The extended disk structure with about 5° width and some humps are observed. In addition, complex features are well resolved in the galactic centre region because of a low airglow level attained at a high elevation angle. Maps obtained with finer fields of view show similar features but a more pronounced structure near the galactic centre. This implies that the derived surface brightness results from an extended source and is not influenced by nearby bright stars; this can be partly confirmed using the data of the 2.2  $\mu$ m survey of stars<sup>8,9</sup>.

Figure 2 shows the longitudinal distribution of the peak surface brightness near the galactic equator at 2.4  $\mu$ m observed with the 1.7° field of view. The error due to detector noise and a variation of the airglow level is as small as  $3 \times 10^{-11} \text{ W cm}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ .

Humps at  $l = -13^\circ, -22^\circ, -45^\circ$  were first found in this experiment; similar humps at  $l = 16^\circ, 27^\circ, 47^\circ$  had been detected during previous observations. The hump at  $l = 27^\circ$  indicates a strong concentration of IR sources in the region at  $\sim 5$  kpc from the galactic centre; molecular clouds, H II regions and other young objects are also concentrated in this '5 kpc ring'. However, our present result indicates that the surface brightness is distributed not symmetrically, and suggests the spiral structure of the Galaxy. Although the velocity distribution of CO clouds does not clearly show the ridge of the spiral structure<sup>10</sup>, the 5-kpc ring may represent part of the bright galactic arm.

In Fig. 2, G and S indicate the tangential directions to the galactic arms modelled from the distribution of large H II regions<sup>11</sup> and from the density wave theory mainly based on H I observations<sup>12</sup> respectively. The agreement is not good over the entire galactic plane, the discrepancy being larger for the southern galactic plane. However, a pair of innermost humps at

**Fig. 1** The contour map of 2.4  $\mu\text{m}$  surface brightness with 1.7° field of view. The shaded area indicates the field of view used.

$l = 16^\circ$  and  $-13^\circ$  would indicate the existence of the dispersion ring. Observed asymmetry is essentially consistent with the ellipticity and the direction of the major axis in the model<sup>12</sup>.

Figure 2b shows the relative colour,  $[m(2.4 \mu\text{m}) - m(3.4 \mu\text{m})]$  at the surface brightness peak plotted against longitude, with the normalisation to  $[m(2.4 \mu\text{m}) - m(3.4 \mu\text{m})] = 0$  at  $l = 0^\circ$ . A colour difference of  $\sim 0.3$  mag is found between the disk and galactic centre directions; that is, the disk is redder than the central region. The colour difference of 0.3 mag corresponds to the excess interstellar extinction of  $A_V \sim 10$  mag towards the disk direction over the galactic centre direction, consistent with the model of the distribution of interstellar dust<sup>7</sup>.

The latitude of the peak surface brightness for each scan is also plotted in Fig. 2c. Peak surface brightness is situated  $\sim 0.5^\circ$  below the galactic equator for  $10^\circ < l < 30^\circ$  and  $\sim 0.5^\circ$  above the galactic equator for  $335^\circ < l < 340^\circ$ . Note that these displacements seem to be associated with bright humps at  $l = 27^\circ$  and  $-22^\circ$ . For the northern galactic plane, similar displacements are

observed for the 5 kpc ring for CO clouds<sup>13</sup>, H II regions<sup>14</sup>, and OH-IR sources<sup>15</sup>.

Another interesting feature is the latitude distribution of surface brightness. Even for the finest field of view at 2.4  $\mu\text{m}$ , we do not find the absorbing feature which might be expected from a strong concentration of absorbing matter in the plane. This implies that the IR sources are also concentrated in the galactic plane, supporting the view that they are young objects, probably M supergiants. At 3.4  $\mu\text{m}$  the galactic plane is narrower than that at 2.4  $\mu\text{m}$ . This difference can be explained by weaker interstellar extinction at 3.4  $\mu\text{m}$ .

The galactic centre region reveals several interesting features. First, the 2.4  $\mu\text{m}$  plot within  $4^\circ$  from the galactic centre is asymmetric with respect to the galactic plane, similar to the tilted disk modelled from the H I observations<sup>16</sup>. Second, two features extend in longitude up to  $l = 7^\circ$  and  $-6^\circ$ . The feature at  $l \sim 355^\circ$  was detected by previous observations<sup>3,4</sup> as an extended IR source; its counterpart with a similar, though weaker, feature

**Fig. 2** The longitude distribution of the peak surface brightness at 2.4  $\mu\text{m}$  for each scan with 1.7° field of view. ●, The present result; ○, our previous observations<sup>1,2,4</sup>, where they have not been superseded by the present work. Arrows show the positions of characteristic humps. S and G indicate the tangential directions according to different galactic arm models. b, The longitude dependence of relative colour,  $[m(2.4 \mu\text{m}) - m(3.4 \mu\text{m})]$ , at the peak, normalised at  $l = 0^\circ$ . c, The latitude of the peak surface brightness for each scan.

**Fig. 3** *a*, The longitude distributions ( $b = 0$ ); *b*, the latitude distributions ( $l = 0$ ) of surface brightness at 2.4  $\mu\text{m}$  and 3.4  $\mu\text{m}$  on the galactic plane with 1.7° and 2° fields of view, respectively.

is first found at  $l = +6^\circ$ . This asymmetrical structure suggests that there exists a disk-like component on which the central bulge is superimposed. Third, there are two dark lanes intruding into the plane from below. The southern one is more pronounced and was detected by our previous observation<sup>4</sup>. These dark lanes may be partly explained by the dark clouds between the galactic centre and the Sun  $0.5^\circ$  below the  $b = 0^\circ$  plane<sup>13</sup>. Finally, Fig. 3 compares the 2.4 and 3.4  $\mu\text{m}$  data, and they show no appreciable colour variation with longitude, but an excess of 2.4  $\mu\text{m}$  flux for  $b < 0$ .

## Stable 'pancake' distributions of low energy electrons in the plasma trough

WAVE-PARTICLE interactions have been recognised as the likely key to processes which control the dynamics of the Earth's magnetosphere and trigger auroral precipitation<sup>1</sup>. The GEOS 1 and GEOS 2 satellites carry wave and particle measuring instruments which permit a full exploration of interactions occurring in the equatorial magnetosphere out to a distance of 7  $R_E$  (ref. 2). The large variety of plasma wave phenomena has been reviewed by Southwood<sup>3</sup> and Christiansen *et al.*<sup>4</sup> have reported on emissions observed by GEOS 1. The geostationary position was expected to be an oasis of important wave-particle phenomena because it is in that region of the magnetosphere where cold plasma, originating from the ionosphere, mixes with hot plasma-sheet particles<sup>5</sup>. The large amount of data now emanating from GEOS 2 more than meets expectations, a number of relatively exotic particle distributions are being observed together with clearly associated wave spectra. Here, we report on one significant example.

The UCSD spectrometers aboard the ATS 5 and ATS 6 satellites yielded a magnificent data set for the particle environment at 6.6  $R_E$  (ref. 6). This, together with data from satellites in highly eccentric orbits (such as OGO 5 and Explorer 45), has led to an established picture of particle convection, substorm injection and subsequent dispersion, excursion of the plasmopause boundary and ring current evolution.

Theories of wave generation depend on the creation of instabilities and call for anisotropic particle populations; a distribution function  $f(E)$  with  $df/dv_{\perp} > 0$  is particularly sought. The inevitable loss cone is an obvious candidate source, it can be enlarged by pitch angle diffusion<sup>7</sup>; also the inward convection from the tail generates thermal anisotropy ( $T_{\perp} > T_{\parallel}$ ) but the key parameter is probably the ratio between the densities of 'cold' and 'warm' plasma components. Sufficient cold electrons are required for wave development but too many will damp the unstable mode<sup>8</sup>.

The suprathermal plasma analysers (SPAs) on GEOS 2 have regularly detected a population of electrons over 50 eV which are confined to pitch angles near  $90^\circ$ —a 'pancake' distribution. These particles can be observed near the geomagnetic equator for several hours a day but the dependence on local time is variable, as are the intensity profile and energy spectrum. GEOS also gives the first reliable measurements of cold plasma density near 6.6  $R_E$  and a preliminary description of these new results is presented here. Electrostatic emissions near the half harmonics of the electron-cyclotron frequency are commonly observed near the geomagnetic equator<sup>9</sup>, Gough *et al.*<sup>10</sup> present further evidence for observed correlations but a firm conclusion on cause and effect is not yet clear.

Figure 1 shows the GEOS spacecraft illustrating the position and viewing directions of the SPA sensors which incorporate simple hemispherical electrostatic analysers<sup>11</sup>. The isolated boom mounting of the sensor unit with the utilisation of a bias voltage to overcome the satellite floating potential (a few volts positive) allows the collection of cold protons, the complex sheath structure obviously influences the detected fluxes but in-flight calibration is available in the plasma frequency determination from the wave experiment<sup>4</sup>. The conducting surface of GEOS seems to eliminate the problem of differential charging

Fig. 1 GEOS satellite showing the position of the suprathermal plasma analysers.

seen on ATS<sup>12</sup> and this is crucial for these very low energy measurements. One analyser views parallel to the satellite spin axis but this is seldom magnetic field-aligned. In fact the axis of GEOS 2 is usually between  $10^\circ$  and  $15^\circ$  ( $\theta_B$ ) from the field direction and consequently the radial analyser, scanning pitch angles between  $(80 - \theta_B)$  and  $(80 + \theta_B)$  during a 6 s spin period, is ideally pointed to detect pancake distributions. Sixty-four energy channels ( $\Delta E/E = 0.11$ ), logarithmically spaced, cover the full range of 0.5–500 eV but below 20 eV satellite emitted photoelectrons mask the ambient fluxes. It takes about 3 min to obtain a full coverage of energy (20–500 eV) over the available pitch angles.

Figures 2 and 3 show the energy dependence of the pancake distribution by comparing three selected pitch angles ( $\alpha \leq 90^\circ$ )

Fig. 2 Energy spectra for pitch angles:  $90^\circ$  (●);  $69^\circ$  (Δ);  $12^\circ$  (×) taken from detector viewing parallel to spin axis. (2 August 1978 at 5.05 UT;  $0.75^\circ$  N,  $8.8^\circ$  E)

and three selected energy channels. Count rates have been converted to differential energy flux and data from the parallel analyser ( $\alpha = \theta_B = 12^\circ$ ) are included to allow interpolation to small pitch angles. Although the form of the distribution is quite variable, these curves are typical; both the peak flux and the maximum anisotropy often appear below 500 eV, the anisotropy tends to vanish at energies less than 100 eV but here the photoelectrons become significant. The degree of anisotropy can be assessed by fitting a  $\sin^n \alpha$  function; where  $n$  takes a value of 10–20 at the peak the electrons are confined to pitch angles very close to  $90^\circ$ . The analyser acceptance angles (see Fig. 1) do produce some instrumental broadening of the feature. The

Fig. 3 Pitch angle distributions for energy channels: 211 (Δ); 509 (×); 98 (●) eV.

phase space density of the  $90^\circ$  electrons does not exhibit a positive slope when plotted against energy.

The pancake population is generally observed by GEOS 2 during the morning hours. Near local midnight the SPAs detect plasma-sheet electrons which are isotropic, the differential fluxes increase with energy but the maximum is obviously well above our 500 eV limit. Near noon or later, GEOS 2 regularly encounters a cold plasma enhancement with density  $N_i$  of  $50 \text{ cm}^{-3}$  or more. It is not always clear whether these are excursions into the plasmasphere or through detached regions. Between the two, in the morningside plasma trough, the  $\alpha = 90^\circ$  electrons can persist for many hours. To search for possible correlation with electrostatic wave emission, a period of 7 days in August 1978 has been studied and Fig. 4 summarises the results. The geomagnetic planetary index  $K_p$  reached 5 on 12 August but the other days were fairly quiet. The magnetic field briefly departed from a dipolar configuration on only three occasions;  $V$ ,  $D$ ,  $H$  components supplied by Mariani have been used to compute  $\lambda = \tan^{-1} [-V/2H]$  as an estimate of an effective magnetic latitude; this suggests that GEOS 2 was within  $3^\circ$  of the equator for most of the period. The cold plasma density was determined by using a sensor bias of  $-28 \text{ V}$  and calibrating maximum count rates with reference to appropriate plasma frequency measurements; no attempt has yet been made to analyse the spectra but it is clear that the temperature cannot be significantly greater than 1 eV. The plasmaspheric passages tend to be earlier than would be consistent with an evening bulge

Fig. 4 One week's data from GEOS 2 showing the appearance of pancake electron distributions in relation to cold plasma enhancements and ' $3/2 f_{ce}$ ' emissions.

and  $N_1$  can be  $\sim 2 \text{ cm}^{-3}$  or more all around the orbit when  $K_p$  remains small. At such times the total energy flux for electrons between 50 and 500 eV shows that plasma-sheet interceptions can be very short or even non-existent. The flux for  $\alpha = 90^\circ$  divided by that for  $\alpha = 70^\circ$  provides an anisotropy index which shows the presence of the pancake distribution. The latter normally builds up during the morning hours and disappears at a plasmopause entry, there can be a sharp cut off as on 17 August but on the quiet days the pancakes persisted as  $N_1$  did not exceed  $10 \text{ cm}^{-3}$ . The growth of the anisotropic distributions is usually from 500 eV downwards in energy and it will be interesting to examine other GEOS data (S310) to find the high energy limit.

Detection of strong electron cyclotron harmonic emissions (' $3/2 f_{ce}$ ') is indicated on Fig. 4 by the identification of times for which the integrated spectral density between  $f_{ce}$  and  $2f_{ce}$  exceeds  $10^{-9} \text{ (V}^2 \text{ m}^{-2})$ . A high anisotropy index ( $>3$ ) when combined with an absence of dense cold plasma ( $<10 \text{ cm}^{-3}$ ) generally corresponds with strong wave generation. This striking coincidence of the pancakes and the ECH waves is a feature of all GEOS 1 and GEOS 2 data although there are a few obvious exceptions which need explanation. Gough *et al.*<sup>10</sup> describe the complexity of the wave spectra and introduce a classification as a starting point in ordering the data; evidence of interaction is clearly identified.

We have given an early announcement of a magnetospheric particle population which must be an important quiet-time feature of the equatorial plasma trough. It has not been reported previously; GEOS 2 is the first high altitude satellite, with suitable low energy particle detectors, stationed close to the geomagnetic equator. The pancake distributions almost certainly result from wave interaction; the observed electro-

static waves seem to be responsible but the interaction is not 'local' in that the drift path of the electrons is not along the satellite orbit. The stability of the consequent distribution and the inherent equatorial confinement could then determine the morphology of the class III waves<sup>10</sup>. A detailed study is under way and we will be disappointed if this is not matched by renewed activity on the part of theoreticians.

## Interaction of electrostatic waves with warm electrons at the geomagnetic equator

WE present here observations of electron-cyclotron harmonic (ECH) waves occurring in the vicinity of the geomagnetic equator at 6.6 Earth's radii, and discuss their relevance to the morphology of electron distributions (with energies below 500 eV) observed simultaneously<sup>1</sup>.

The observations were carried out during the slow crossing of the geomagnetic equator (4–13 August 1978) by the GEOS 2 satellite, launched into a geostationary orbit on 28 July 1978. The earlier GEOS 1 satellite, which covered a wider latitude range in a non-geostationary orbit, showed that a particular class of dayside ECH wave emissions are confined within a couple of degrees about the geomagnetic equator<sup>2</sup>.

The ECH instability, characterised by emission in frequency bands between the harmonics of the electron gyrofrequency  $f_{ce}$ , has been observed in a variety of spectral forms by a number of magnetospheric satellites<sup>3–5</sup>. However, because the GEOS series combines unique active plasma diagnostic techniques<sup>6–8</sup> with natural wave detection<sup>9</sup> the observed natural emissions can be much more readily related to local plasma parameters than can results from earlier spacecraft.

It has been shown theoretically that the ECH instability can be explained in terms of a 'basic' two-component plasma model<sup>10–15</sup>: the free energy for wave amplification is provided by a hot loss-cone component ( $T_h \sim 100$  eV) while a second cool component ( $T_c \sim 1$  eV) presumably of ionospheric origin, aids destabilisation. For a wide range of values of the ratio of the cool to the hot electron density,  $N_c/N_h$ , the dominant instability frequency occurs close to the cool plasma upper hybrid frequency  $f_{uhc} = (f_{pc}^2 + f_{ce}^2)^{1/2}$ , where  $f_{pc}$  is the cool plasma frequency. Other spectral features can occupy gyroharmonic bands below and above  $f_{uhc}$ .

Because the value of the cold plasma density strongly

influences the observed spectral characteristics of the ECH waves, it has been used as a guideline for classification schemes<sup>14</sup> including the one given below.

Note that at the geostationary orbit  $f_{ce}$  lies typically between 2 and 3 kHz, while  $f_{pc}$  spans a wide range from below  $f_{ce}$  up to above the maximum observable frequency of 77 kHz.

A spectrogram of wave data from GEOS 2 for the period covering the last hours of the 6 August and the full orbit for the 7 August 1978 (Fig. 1) shows the four main classes of ECH emissions detected.

Class I emissions, characterised by a single frequency band just above  $f_{ce}$  (typically  $1.2 f_{ce}$ ), occur around local midnight where the spacecraft encounters the plasma sheet, dominated by hot plasma convected in from the geomagnetic tail ( $f_{pc} < f_{ce}$ ) and can be seen about 00.00 UT and 22.00–24.00 UT on the 7 August.

Class II emissions are briefly seen as the satellite moves into the morning sector, and the cold plasma density increases. Here the dominant intensity of the emission still occupies the lowest gyroharmonic band ( $f_{pc} \sim f_{ce}$ ) but is accompanied by weaker, higher harmonic structures.

Class III emissions, can be seen for a long period after 01.00 UT, when the cold plasma density rises ( $f_{pc} > 2f_{ce}$ ). The dominant frequency is sometimes banded in a complex fashion, and increases to  $\sim 25$  kHz around 19.00 UT, with accompanying  $(n + \frac{1}{2})f_{ce}$  emissions between low gyroharmonics. On board plasma diagnostics show that during this period  $f_{uhc}$  is within 1 kHz of the dominant emission band.

Class IV emission<sup>10</sup>, is a weak emission in the vicinity of the  $f_{uhc}$  which is observed after 19.00 UT, when the low harmonic signals at  $\sim 3/2, 5/2 f_{ce}$  disappear.

This particular orbit does not show the usual encounter with the denser evening bulge, but the typical class IV and class III emissions associated with it can just be seen during the last hours of the 6 August (extreme left of Fig. 1).

Some feeling for relative emission intensities can be gained from the plot at the bottom of Fig. 1. The upper trace is the integrated spectral density for frequencies above  $f_{ce}$ , and the lower trace is the spectral density integrated over the range from

**Fig. 1** Grey-scaled GEOS 2 electric field data for 7 August 1978 plotted with frequency against Universal time. The lower trace shows the integrated spectral densities for all electrostatic waves above the gyrofrequency. The lowest line is that from  $f_{ce}$  to  $2f_{ce}$  only. Geomagnetic LT is UT + 1 h.

**Fig. 2** All GEOS 1 observations (excluding storm periods) of type III electrostatic emissions plotted as a function of geomagnetic latitude and geomagnetic local time. Closed line is limit of observations. McIlwain  $L$  value and day number at which the satellite crossed geomagnetic equator are indicated below.

$f_{ce}$  to  $2f_{ce}$  only. Note that the spectral density peaks twice per orbit, once around midnight for class I ( $E \sim 1 \text{ mV m}^{-1}$ ) and once in the morning-midday region for class III, when the signals are so strong ( $E > 3 \text{ mV m}^{-1}$ ) that the wave detector saturates and harmonic generation can be observed.

The distribution of class III events (enhanced upper hybrid with  $3/2 f_{ce}$  features) reported recently for dayside emissions<sup>2</sup> is shown in Figs 2 and 3, using data from GEOS 1 (perigee 2,000 km, apogee 42,000 km,  $-10^\circ < \lambda_m < 30^\circ$ , taking in excess of a year to survey all local times). This analysis covers 14 months of satellite operation, and class III events were recorded during the vast majority of equator crossings (Fig. 2) in which the wave analysers were in the appropriate observing modes. Those emissions which occurred far from the model field equator were accompanied by the largest differences between the field observed at the spacecraft and the modelled geomagnetic field, suggesting that in these cases the field lines were distorted.

Figure 3 further describes the equatorial confinement of the class III emissions, by showing the distribution of emission widths (Fig. 3a) and the location of the emission centres, both plotted as a function of geomagnetic latitude. Approximately 75% of the emissions were  $< 4^\circ$  in latitudinal extent, and 75% were centred between  $-2^\circ < \lambda_m < +3^\circ$ .

In August 1978 GEOS 2 drifted slowly through the geomagnetic equator towards its present position of  $\lambda_m = -3^\circ$ , and during this period Wrenn, Johnson and Sojka<sup>1</sup> report frequent observations of remarkable electron distribution features, which show electrons in the hundreds of eV range to be confined to pitch angles within a few degrees of  $90^\circ$  ('pancake' distributions). Figure 4 summarises 10 d of GEOS 2 observations around the geomagnetic equator, and compares plots of hourly means of the spectral density of ECH waves, versus hourly means of the anisotropy index<sup>1</sup> for warm electrons with energies  $< 500 \text{ eV}$ . These points incorporate all data received when the two experiments (wave and particle detectors) were in the appropriate operating modes. A striking feature of Fig. 4 is that as the ECH spectral density increases there is a well defined maximum of observable anisotropy index. In particular this behaviour is strongly related to that of class III emissions (black dots) which, as pointed out above, occur mainly between 04.00 and 13.00 UT. The narrow pitch angle distributions therefore tend not to occur in the midnight sector where class I and II emissions predominate. Furthermore, from a survey of GEOS 1 data they show the same sort of equatorial confinement as class III emissions<sup>1</sup>.

In seeking an explanation for these observations it is important to note that the combination of nightside convection of plasma sheet electrons with collisional diffusion during subsequent convection through the dayside, cannot produce

such highly pitch-angle peaked distributions. Inward convection can produce a loss-cone distribution, and therefore a source of free energy for ECH wave amplification<sup>16</sup>.

In the amplification process, resonant electrons, which satisfy the condition  $\omega - k_{\parallel} v_{\parallel} = \pm n \omega_{ce}$  are scattered in velocity space, the important exceptions being those with small  $v_{\parallel}$  (that is large pitch angles), which are relatively unaffected. Quasilinear theories show this clearly<sup>17</sup> and predict among other things, that for wave fields of  $\sim 1 \text{ mV m}^{-1}$  hot electrons can be rapidly scattered into the loss cone<sup>13</sup>.

We suggest that the 'pancake' distributions observed in conjunction with strong ECH wave activity are a remnant feature of the electron distribution, resulting from this interaction. Their evolution can be pictured as beginning with the class I emissions which are amplified by electrons freshly convected into the nightside magnetosphere, and progressing through further wave-particle interactions during the subsequent convection of the electrons around into the dayside magnetosphere. Since the pancake distributions can contribute to further destabilisation of the waves<sup>18</sup>, their presence may also be a significant factor in the equatorial confinement of class III emissions.

**Fig. 3** a, Distribution of widths of GEOS 1 observed type III emission in degrees geomagnetic latitude. Also indicated is the equivalent equatorial pitch angle range assuming the centre of the emission is at the minimum B equator. b, Distribution of centres of type III emissions in degrees geomagnetic latitudes from field model equator<sup>20</sup>.

**Fig. 4** GEOS 2 Hourly means of the integrated spectral density above the gyrofrequency plotted against the mean anisotropy of electrons below 500 eV between 14.44 UT on 4 August and 21.27 on 13 August. Class of emission: ○, class I and II; ●, class III; ▲, class IV; ■, class IV plasmasphere.

The role of ECH wave-particle interactions in providing the electron component of diffuse auroral precipitation has been much discussed in recent years<sup>3,17,19</sup>. We hope to extend our studies into this area shortly.

This research has been performed as part of the GEOS S-300 wave experiment collaboration. We thank R. Gendrin and K. Ronnmark for helpful comments, and the staff at CNES, Toulouse, for data tapes. Our work is supported by the SRC.

## Contribution of volatile petroleum hydrocarbons to the organic carbon budget of an estuary

STUDIES on oil pollution of the marine environment have received considerable attention<sup>1</sup>, especially work involving the effects of oil spills resulting from tanker accidents such as the *Amoco Cadiz*<sup>2</sup>. Very little attention, however, has been devoted to assessing the importance of low level, continuous, inputs of petroleum hydrocarbons to productive estuarine environments. Investigations of hydrocarbon contamination of estuaries and rivers have concentrated mainly on the impact of non-volatile hydrocarbons<sup>3</sup> (that is, those hydrocarbons having more than 15 carbon atoms) rather than the volatile hydrocarbons emanating from sewage discharges and industrial effluents such as petroleum refineries. We discuss here the occurrence and possible fate of these volatile hydrocarbons in estuarine systems.

During research in determining an organic carbon budget for Southampton Water estuary, the seasonal fluctuations in planktonic respiration and photosynthesis were studied. Characteristically, we observed a pronounced seasonal cycle in planktonic photosynthesis with intense activity in the mid-summer months and little in the winter. In contrast, planktonic respiration showed a less pronounced seasonal change, respiration being sustained through the winter months (Fig. 1). It has been argued that the winter respiration is supported by the external inputs (sewage, rivers and industrial effluents)<sup>4</sup> and this would require a daily input with a biological oxygen demand (BOD) equivalent to 30-40 tonnes of O<sub>2</sub> per day. It may be seen that cumulative 5 d BOD at 15 °C is of this order (Table 1). The largest single industrial input to the estuary is the oil effluent from the Esso refinery at Fawley (the largest refinery in the UK with a refining capacity of 20 Mtonne yr<sup>-1</sup>). The refinery effluent accounts for 75% of the total industrially derived carbon discharged to the estuary yearly<sup>4</sup>.

A detailed study has been made of the non-volatile fraction of the refinery effluent and the role and fate of these compounds in the estuarine environment<sup>5</sup>. These studies showed that the non-volatile fraction, the most commonly studied part of oil, could not account for the observed respiration rates. This led us to hypothesise that the volatile hydrocarbon fraction, which usually receives little attention, may play an important role in, at least, this estuarine ecosystem.

Previous work on the biodegradation of petroleum hydrocarbons has been carried out using standard microbiological techniques<sup>6</sup> and it is widely accepted that marine microbial organisms can degrade oil<sup>7</sup>. The quantity and diversity of oil degraders present in marine systems are more likely to be higher for areas with continuous hydrocarbon discharges than pristine environments<sup>8</sup>. The likelihood of high numbers of petroleum utilising bacteria would be even greater for estuaries which contain high concentrations of other heterotrophs<sup>9</sup>. One would therefore expect that with such a large continuous input of petroleum hydrocarbons from the Fawley refinery over the past 25 yr, there would be a very significant resident population of specialised oil degraders at the refinery outfall area as well as in the estuary itself.

To investigate the degradation of the non-volatile fraction of the refinery effluent, we used large glass containers and monitored hydrocarbon concentrations using gas, solid-liquid<sup>10</sup> and thin layer<sup>11</sup> chromatography. Quantification of compounds that were separated into broad categories of compound type was accomplished by combustion in a total carbon analyser<sup>5</sup>.

The average total non-volatile hydrocarbon content of the refinery effluent determined by the above method was 3 mg C per l, giving a daily input of hydrocarbons of about 1 tonne C per day. The results of our biodegradation experiments indicated that only 34% of the non-volatile hydrocarbon fraction was degraded at 15 °C over the 5 d BOD period with more

Fig. 1 Oxygen flux due to respiration and photosynthesis for Southampton Water estuary. ○, Gross photosynthesis; ■, respiration 1974–75.

than half the loss from the experimental containers attributable to evaporation processes. Assuming a respiratory quotient of 0.66 for the respiration of hydrocarbons, one may estimate the BOD stemming from the oxidation of the non-volatile fraction to be in the vicinity of 1 tonne  $O_2$  per day. Thus it seems that the degradation of the non-volatile fraction of the refinery effluent could not account for the high BOD of 40–100  $mg O_2$  per l of refinery effluent nor could it account for the high BOD in the estuary during the winter months. Due to the possible importance of this volatile fraction, we attempted to obtain more information on the compounds in this fraction of the refinery effluent.

We analysed the refinery effluent by the standard API method 733–758 for refinery waste water used by the refinery for its monitoring programme. This involved quantification of a carbon tetrachloride extract by IR spectrophotometry at  $2,930\text{ cm}^{-1}$  against a standard slop oil collected from the API gravity separators within the refinery complex. The results of these analyses indicated that the estuary received an average loading of 8–10 tonne of material per day as determined by this method. When the carbon tetrachloride extracts were evaporated at  $40^\circ\text{C}$  under vacuum and then redissolved in carbon tetrachloride and measured as before, the levels returned to 1–2 tonne per day. This was consistent with the results determined by the TLC/combustion method described previously. Gas chromatograms of the pre-evaporated and evaporated fraction are given (Fig. 2). Much of the extremely volatile material (hydrocarbons having 5 or less carbon atoms) is masked by the large solvent front at the start of the temperature programme. Ultraviolet (UV) analysis at 254 nm against the same standard

indicated that the removal of UV absorbing material (mainly aromatics and olefins) was similar in magnitude to those compounds absorbing at the  $2,930\text{ cm}^{-1}$  region of the IR. This tentatively indicated that the refinery effluent contained both aliphatic and aromatic compounds in the volatile fraction.

In an attempt to characterise the volatile fraction in more detail we used a cryogenic trapping system<sup>12</sup>. Volatile compounds were trapped in loops cooled by solid  $CO_2$  and analysed by gas chromatography (GC) and gas chromatography–mass spectrometry (GC–MS). This yielded a wide range of volatile *n*-alkane and aromatic hydrocarbons. Aromatics such as benzene, toluene and xylene were present in concentrations of 120, 211 and  $562\text{ }\mu\text{g l}^{-1}$  respectively, indicating the importance of these compounds to the whole refinery input.

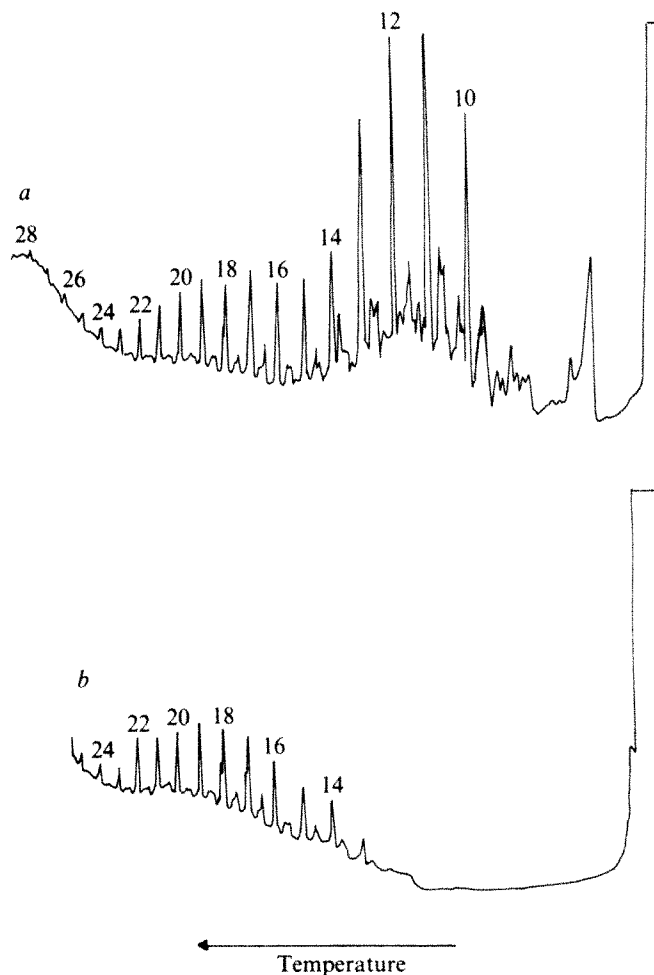

Fig. 2 Gas chromatograms of a, the total (volatile + non-volatile) compared with b, the non-volatile hydrocarbon composition of refinery effluent.

One would expect the residence time of these compounds in the estuarine environment to be similar to that of oceanic environments, aside from the obvious possibility of rapid biodegradation due to increased microbiological activity. For example, orders of magnitude changes in water concentrations of ethane, propane, butane and pentane were found over baseline in the proximity of an oil slick<sup>13</sup>. Sackett and Brooks also report volatile hydrocarbons present 8 km from an underwater drilling rig; concentrations of ethane alone were as high as  $0.3\text{ mg l}^{-1}$ .

The solution mechanism of these volatile hydrocarbons is dependent on the solubilities of the compounds in water relative to their vapour pressures. Also, as molecular weights increase more material is partitioned into the gas phase<sup>14</sup>. With petroleum hydrocarbons, partitioning into the gas phase decreases in the order of *n*-alkanes, olefins, cyclo-alkanes and

Table 1 Sources of organic material in Southampton Water estimated for 1974<sup>17</sup>

	Annual input (tonne C $\text{yr}^{-1}$ )	Percentage of total annual organic input	Daily winter BOD
Phytoplankton	3,000	23%	<5.0
Rivers	1,400	11%	4.2
Sewage	1,580	12%	3.2
Industry (Petroleum 75%)	6,800	53% (Petroleum 40%)	37.0

River input sampled upstream of major sewage and industrial outfalls.

aromatics<sup>15</sup>. McAuliffe<sup>15</sup> states that these volatile hydrocarbons remaining in the water column are eventually removed through biodegradation; we feel that this is also the fate of volatile hydrocarbons in Southampton Water.

In conclusion, the data that we have accumulated during 3 years on Southampton Water estuary suggest that the volatile compounds found in industrial effluents play a significant part in the whole carbon balance of the estuarine ecosystem. The importance of volatile fractions of petroleum hydrocarbons with regard to industrial discharges to estuaries has, to some extent, been overlooked in the past. There is evidence that these hydrocarbons, especially the aromatic component, are toxic to marine life<sup>16</sup>. These considerations indicate the need for more work in valuable estuarine areas to understand the occurrence, fate and impact of these volatile compounds.

## Transformation of goethite to maghaemite in CsI disks

THE formation and stability of  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> (maghaemite) is still a puzzle, as this oxide is metastable with respect to its isomorphic form  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> (haematite). However, there are increasing reports about its natural occurrence in certain soils and sediments (see ref. 1 and refs therein). Maghaemite, like magnetite, Fe<sub>3</sub>O<sub>4</sub>, is ferrimagnetic and its artificial occurrence may therefore be important in carrying out magnetic concentrations in various processes of iron ores industry<sup>2</sup>; as well as finding widespread application in the electronic industry<sup>3</sup>. The artificial preparation of maghaemite is usually carried out by low temperature dehydration of lepidocrocite<sup>4</sup>,  $\gamma$ -FeOOH, or careful oxidation of powdered magnetite<sup>5,6</sup>.

Goethite,  $\alpha$ -FeOOH, heated in the presence of organic matter to 300°C, may also be transformed into maghaemite<sup>7,8</sup>. The optimal conditions for obtaining maghaemite in soils is by heating them in nitrogen, then in air at about 550 °C, which is the

†Protohaematite (b) is obtained by heating goethite in CsI disk to 450 °C.

temperature at which the organic matter most readily produces a reducing environment<sup>9</sup>. When heating the soils in air the formation of maghaemite is negligible. The mechanism suggested for the last reactions in soil, is as follows<sup>1</sup>: gases such as carbon monoxide, produced by the combustion of soil organic matter, reduces finely divided iron oxides and hydroxides to magnetite and on cooling the latter may be subsequently oxidised to maghaemite when air enters the matrix. Normally, thermal treatment of goethite at temperatures 200-600 °C in the absence of organic matter results in a poorly crystalline form of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> which is defined here as protohaematite and which at higher temperatures is converted into the well ordered crystalline variety of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, known as haematite. We show here that maghaemite can be obtained by heating goethite or protohaematite in CsI disks in the absence of organic matter. IR spectroscopy has been previously used successfully to differentiate unambiguously between magnetite, maghaemite and haematite<sup>3</sup>, as well as between protohaematite and haematite<sup>10</sup>.

In the present study the transformation of synthetic goethite to maghaemite in CsI disks was followed by IR absorption spectroscopy and supported by magnetic evidence. Disks of 13 mm diameter were prepared by hand grinding 0.5-1.5 mg synthetic goethite in 400 mg CsI and pressing at 30 ton for 30 s. For the reaction to occur, every disk must be reground and re-pressed at least three times. The optimal conditions were: heating the disks to 250 °C for one night and then at 500 °C during several nights. Alternatively, the disks were directly heated to 500 °C, but in the latter case the results were less satisfactory. Each day the disks were re-pressed and IR spectra were recorded at ambient temperature using a Perkin-Elmer 283 IR spectrophotometer. Some representative IR spectra are shown in Fig. 1.

The spectrum obtained after heating the goethite disk for one night at 250°C is characteristic of protohaematite (Fig. 1a). This indicates that at the initial stage, goethite is transformed to protohaematite at this temperature. When the same disk is then heated at 500 °C during one day (24 h), a different spectrum results, presumably corresponding to a transitional oxide (Fig. 1b). This spectrum does not resemble a spectrum of magnetite<sup>3</sup> nor that of wustite<sup>11</sup>. On further heating of the disk at 500 °C this transitional oxide is transformed to maghaemite, as inferred from the corresponding IR spectrum (Fig. 1c). Additional evidence for this transformation is that the disk is attracted by a magnet, whereas disks of goethite in CsI or of pure CsI do not show magnetic activity in the presence of the same magnet.

Unsuccessful attempts were made to obtain maghaemite: (1) from more concentrated CsI disks of goethite; (2) from disks which were not reground and repressed for several times even after long grinding periods (up to 30 min); (3) from powders resulting after the third repressing and fourth regrounding of the disks, when the powders were consecutively heated to 250 and 500 °C; (4) if the temperature of the second stage heating was below 500 °C. In (1), (2) and (3) protohaematite was the main product of the thermal treatment; in (4) the transitional oxide was the main product at >400 °C.

**Fig. 1** IR spectra of iron oxides in CsI disks: *a*, protohaematite obtained by heating goethite disk one day at 250 °C; *b*, transition iron oxide obtained by heating disk *a* 1 d at 500 °C; *c*, maghaemite obtained by heating disk *a* 4 d at 500 °C; *d*, protohaematite obtained by heating goethite powder 5 d at 450 °C; *e*, transition iron oxide obtained by heating disk *d* 1 d at 500 °C; *f* maghaemite obtained by heating disk *d* 14 d at 500 °C. (*f* also contains some of the transition iron oxide; *e* and *f* contain small amounts of protohaematite).

The transformation of protohaematite (obtained by heating goethite powder at 450 °C for 5 days) to maghaemite in CsI disks was also followed by IR spectroscopy (Fig. 1*d, e, f*). Here again, the optimal conditions for obtaining maghaemite are a small oxide concentration, regrinding and re-pressing the disk for at least three times and heating the disk to 500 °C as a whole and not as powder.

As with goethite the transformations of protohaematite into maghaemite in CsI disk also occurs through a transitional oxide. However, bigger amounts of protohaematite remain untransformed after one day heating at 500 °C, compared with the amounts of protohaematite which are found in the goethite disk heated in the same conditions. Moreover, when protohaematite is the starting material the reaction rates are slower. The reaction was completed after less than four days when starting with goethite, but was far from completion even after 14 days when starting with protohaematite (compare Fig. 1*c* and *f*).

The thermal transformations of haematite (obtained by heating goethite powder at 1,000 °C) and of natural Al-bearing goethite (from Venezuelan laterites<sup>12</sup>) to maghaemite in CsI disks were unsuccessful in the present experimental conditions.

The protohaematite → maghaemite transformation is an epitaxial process in which accord between the initial and resultant lattices occurs in two dimensions. Protohaematite has a hexagonal close-packed oxygen sublattice whereas maghaemite has a cubic one. The ordering of layers shifts from *ababab* in protohaematite to *abcabc* in maghaemite. One would expect that such a shift might occur when the *ababab* association is highly defective and/or the crystal particles are very small, as in the case of protohaematite but not of haematite.

The crystal defects, the degree of crystallinity and the small size of the protohaematite particles cause the X-ray diffraction

peaks to broaden. Protohaematite was prepared by heating gradually to 450 °C a disk composed of 150 mg synthetic goethite and 300 mg CsI (the mixture being ground for 30 min before pressing). Table 1 summarises widths of half heights of the characteristic diffraction peaks showing that there is an inverse correlation between the widths of X-ray diffraction peaks of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and the ease of forming maghaemite. As may be expected from thermodynamic considerations haematite with the highest degree of crystallinity fails to transform into maghaemite, whereas protohaematite formed in a CsI disk and which has the lowest degree of crystallinity, is most easily transformed into maghaemite.

The present study does not enable us to draw a firm conclusion on the stage at which the crystal nuclei of maghaemite are obtained. However, we can suggest that the nucleation of maghaemite occurs in the CsI/Fe<sub>2</sub>O<sub>3</sub> interface because: small particle-size is not sufficient for the reaction to occur; the importance of regrinding and re-pressing; the reaction does not take place in a powdered medium; and other alkali halides (including KI) fail to cause maghaemite to form from goethite or from protohaematite with the same treatments.

## Sequencing of the 3'-terminal region of a 16S rRNA gene from *Zea mays* chloroplast reveals homology with *E. coli* 16S rRNA

CHLOROPLASTS are semi-autonomous organelles which possess their own DNA coding for organelle-specific RNAs and proteins. The translation process within a chloroplast is mediated by its own ribosomes of the 70S type, which are different from the 80S ribosomes of the cytoplasm. In view of this key function of 70S ribosomes for the organelle-specific protein synthesis we have undertaken to analyse rDNA from *Zea mays* chloroplasts at the nucleotide level, as we considered that this should allow a deduction of rRNA primary structures, and analysis of their mode of function and evolutionary relationship. DNA from *Zea mays* chloroplasts is a circular molecule of about 135 kilobase pairs, on which two rRNA coding regions are positioned in opposite orientation within two 22-kilobase pair

Fig. 1 Position of rRNA genes and of fragment *Bam*HI·C/*Hpa*II·E<sub>345</sub> (wavy line) on the physical map of plasmid pZmc134. Subscript numbers of the fragments refer to their approximate size in base pairs.

inverted repeats<sup>1</sup>. Each region includes one copy of a 16S rRNA, a 23S rRNA and a 5S rRNA gene and a spacer between the 16S and 23S rRNA genes. One such rDNA region has been linked to the plasmid vector pMB9 within the *Escherichia coli* clone pZmc134 (ref. 1), and this clone was therefore used for isolation, mapping and sequencing of the respective DNA fragments (Fig. 1)<sup>2</sup>. We present here the sequence coding for the 3'-terminal part of chloroplast 16S rRNA and for the adjacent part of the spacer region, and report that there is extensive homology between this region of 16S rRNA and the 16S rRNA gene from *E. coli*.

Hybridisation<sup>1,2</sup> and fine mapping<sup>2</sup> data indicated that the region coding for the 3' terminus of plastid 16S rRNA is likely to be positioned at one end of fragment *Bam*I·C, which, after further cleavage with the restriction enzyme *Hpa*II, produces the subfragment *Bam*I·C/*Hpa*II·E<sub>345</sub> (Fig. 1). This fragment, characterised by a *Bam*I site at one end and a *Hpa*II site at the other end (Fig. 2), was isolated and used for sequence analysis according to the dimethylsulphate/hydrazine procedure<sup>3</sup> with minor modifications as described<sup>4</sup>. After terminal labelling of this fragment the two labelled ends were separated by cleavage with *Hae*III or *Mbo*II (for position of cleavage sites see Figs 1,

Fig. 2 3'-terminal portions of 16S rRNA genes from *Zea mays* chloroplasts (top row in each line, identical to the nucleotide sequence of fragment *Bam*I·C/*Hpa*II·E<sub>345</sub>) and from *E. coli*<sup>5,6,9,17</sup> (bottom row in each line). The sequences shown are of only one DNA strand, which is the non-coding, RNA-like strand. It should be noted that the sequence of the maize fragment *Bam*I·C/*Hpa*II·E<sub>345</sub> is depicted in opposite polarity to that in Fig. 1. Numbering refers to *E. coli* 16S rDNA<sup>5,9</sup>. The *E. coli* spacer part containing the tRNA<sup>ile</sup> gene is deduced from the tRNA<sup>ile</sup> primary structure<sup>17</sup>. Homologous sequences are marked by boxes. The sequences at the 3' end complementary to initiator regions of prokaryotic mRNAs<sup>7,10,11</sup> are underlined by wavy lines. Triangles within sequences symbolise deleted positions compared with the other DNA.

## Accumulation of an mRNA and protein in interferon-treated Ehrlich ascites tumour cells

INTERFERONS are glycoproteins which are synthesised by various vertebrate cells in response to virus infection or some other stimuli. They are secreted and then interact with other cells and convert these into an antiviral state, in which the multiplication of viruses is impaired<sup>1</sup>. It is thought that transcription and translation are required for the establishment of the antiviral state as actinomycin D or inhibitors of protein synthesis, suitably administered, prevent or delay the effect<sup>2,3</sup>. Results with enucleated cells also support this idea<sup>4</sup>. We show here that treatment of Ehrlich ascites tumour (EAT) cells with highly purified interferon results in the accumulation of a particular mRNA and the corresponding protein within the cells. However, we have not yet identified the function of the induced protein.

Messenger RNA was prepared from monolayers of EAT cells treated with 500 U ml<sup>-1</sup> interferon for 8 h and from control cells and was translated both in the wheat germ system and in the nuclease-treated reticulocyte lysate. The radioactive translation products were analysed by SDS gel electrophoresis (Fig. 1). In the wheat germ translation system (Fig. 1, tracks 1, 2), compared with the mRNA from control cells, the mRNA from interferon-treated cells yields an increased amount of one protein. This protein (Fig. 1, arrow) migrates with a molecular weight of

14,500. Translation of mRNA from cells which have been simultaneously treated with interferon and actinomycin D results in only the control level of the 14,500-MW protein (Fig. 1, track 13). The translation products in the reticulocyte lysate (Fig. 1, tracks 5, 6) extend to a higher molecular weight than those in the wheat germ system but the 14,500-MW region of the gel is obscured by the large amount of non-radioactive globin in the reticulocyte lysate.

To show that the increased production of the 14,500-MW protein was not a consequence of differential post-translational processing, we first translated in the presence of radioactive amino acids separately the mRNA from control cells and the mRNA from interferon-treated cells. Each of these two mixtures was then further incubated with the products obtained by translating mRNA from either control or interferon-treated cells in the presence of non-radioactive amino acids. The second incubations were carried out in the presence of anisomycin to prevent further protein synthesis. There is neither degradation of the radioactive 14,500-MW protein when it is mixed with the non-radioactive translation products of control mRNA (Fig. 1, track 16), nor production of the 14,500-MW protein when the radioactive translation products of control mRNA are mixed with the non-radioactive translation products of the mRNA from the interferon-treated cells (Fig. 1, track 15). These results make it highly likely that treatment of the cells with interferon results in increased accumulation of the mRNA coding for the 14,500-MW protein.

To compare the *in vitro* translation products of mRNA from control cells and mRNA from interferon-treated cells more closely, we analysed them by two dimensional (2D) gel

**Fig. 1** Mouse EAT cells were grown in monolayers in GIBCO F15 medium containing 7.5% fetal calf serum. Mouse interferon ( $0.5-1 \times 10^9$  U mg<sup>-1</sup>) was prepared from EAT cells essentially as described previously<sup>11</sup>. Monolayers of EAT cells were treated as indicated with 500 U ml<sup>-1</sup> interferon for 7.5 h, or with 500 U ml<sup>-1</sup> interferon and 2  $\mu$ g ml<sup>-1</sup> actinomycin D for 7.5 h or kept as controls and then collected into phosphate buffered saline (PBS, 137 mM NaCl, 2.7 mM KCl, 8.1 mM Na<sub>2</sub>HPO<sub>4</sub>, 1.5 mM KH<sub>2</sub>PO<sub>4</sub>, pH 7.2) by scraping with a rubber policeman. The cells were washed twice with PBS, frozen, thawed and extracted twice with 0.15 M NaCl, 10 mM Tris-Cl pH 7.5, 1 mM MgCl<sub>2</sub>, 0.075% Triton X-100. After digestion with 0.3 mg ml<sup>-1</sup> proteinase-K in the presence of 0.5% SDS and 10 mM EDTA at 37 °C for 10 min, total cytoplasmic RNA was extracted by the phenol/chloroform/isoamyl alcohol method<sup>12</sup>. This RNA was fractionated on columns of oligo(dT)-cellulose (Collaborative T2) by application in 0.5 M NaCl, 10 mM Tris-Cl pH 7.5, 0.1% SDS and elution with 10 mM Tris-Cl pH 7.5, 0.1% SDS<sup>13</sup>. After recovery by ethanol precipitation, the unbound [poly(A)]<sup>-</sup> and the bound [poly(A)]<sup>+</sup> fractions were dissolved in water and stored at -70 °C. Eight 150 mm tissue culture dishes of 50% confluent control and interferon-treated cells typically yielded 2.05 mg poly(A)<sup>-</sup> RNA and 0.12 mg poly(A)<sup>+</sup> RNA. A similar quantity of cells treated with interferon and actinomycin D gave 1.57 mg poly(A)<sup>-</sup> RNA and 0.04 mg poly(A)<sup>+</sup> RNA. *In vitro* translations were in the wheat germ system<sup>14</sup> or mRNA-dependent reticulocyte lysate<sup>6</sup> with 150  $\mu$ Ci ml<sup>-1</sup> of a mixture of <sup>35</sup>S-methionine and cysteine as radioactive label. Poly(A)<sup>-</sup> RNA was translated at 500  $\mu$ g ml<sup>-1</sup> and poly(A)<sup>+</sup> RNA at 60  $\mu$ g ml<sup>-1</sup> except in track 13 where poly(A)<sup>+</sup> RNA was at 20  $\mu$ g ml<sup>-1</sup>, reflecting the lower amount of RNA in the actinomycin D-treated cells. After translation at 30 °C for 60 min, aliquots were analysed by SDS gel electrophoresis<sup>6</sup> and fluorographs<sup>15,16</sup> are shown. *a*, Tracks 1, 2, 5, 6 poly(A)<sup>-</sup> RNA, 3, 4, 7, 8 poly(A)<sup>+</sup> RNA, 9, 10 no mRNA was translated in 1, 2, 3, 4, 9 the wheat germ system or 5, 6, 7, 8, 10 the reticulocyte lysate. Tracks 1, 3, 5, 7 are RNA from control cells, 2, 4, 6, 8 RNA from interferon-treated cells. *b*, Translation in wheat germ system of poly(A)<sup>+</sup> RNA from control cells (11), interferon-treated cells (12), cells treated with interferon and actinomycin D (13). Tracks 14-17: poly(A)<sup>+</sup> RNA from control or interferon-treated cells was translated for 60 min in the wheat germ system in the presence of <sup>35</sup>S-methionine and cysteine and then an aliquot of each was mixed with an equal volume of duplicate translations containing either control or interferon-treated cell poly(A)<sup>+</sup> RNA and no radioactive label. These reactions were then further incubated at 30 °C for 45 min in the presence of 0.2 mM anisomycin. Tracks 14, 15 first (labelled) incubation control cell mRNA; tracks 16, 17 first (labelled) incubation interferon treated mRNA; tracks 14, 16 mixed with control cell mRNA translation products; tracks 15, 17 mixed with interferon-treated cell mRNA translation products. The experiments in (*b*) used independent preparations of mRNAs and wheat germ system from those in (*a*). The vertical scale shows the positions to which standard proteins (molecular weights in kilodaltons) migrated on the gel.

**Fig. 2** Poly(A)<sup>+</sup> RNA from *a*, control cells; *b*, cells treated with 500 U ml<sup>-1</sup> interferon for 8 h was translated at 60 µg ml<sup>-1</sup> for 60 min in the wheat germ system with <sup>35</sup>S-methionine and cysteine as radioactive label. Samples were then made up to 9 M urea, 2% ampholines (pH 3–10, Bio-Rad), 1% NP-40, 2.5% 2-mercaptoethanol and analysed by 2D gel electrophoresis as described by O'Farrell<sup>5</sup> except that the isoelectric focusing gels contained 2% Bio-Rad ampholines (pH 3–10) and the second dimension was on non-gradient 15% gels. The figure shows fluorographs of the gels. The equivalence of cm and pH is given in Fig. 3 and the vertical scale shows the positions to which standard proteins (molecular weights given in kilodaltons) migrated on the gel.

electrophoresis<sup>5</sup> (Fig. 2). In this system the 14,500-MW induced protein (arrowed) shows up clearly at pI 7.5. We cannot yet find any other significant difference between the *in vitro* translation products of the two mRNA preparations.

The experiments shown in Fig. 3 were designed to find whether the elevated level of mRNA coding for the 14,500-MW protein is manifested in an increased amount of this protein in interferon-treated cells. EAT cells were treated with interferon

**Fig. 3** EAT cells were treated with interferon and actinomycin D as below and then labelled with 60 µCi ml<sup>-1</sup> of a mixture of <sup>35</sup>S-methionine and cysteine for 1 h. At the end of the labelling the medium was removed, the monolayer was washed with ice-cold PBS and the cells were lysed in 0.4 ml of 9 M urea, 2% NP-40 per 60-mm dish. The viscous lysate was sonicated for about 15 s to disperse the DNA. Samples of 10 µl of the lysate were made up to 9 M urea, 2% ampholines (pH 3–10, Bio-Rad), 1% NP-40, 2.5% 2-mercaptoethanol and analysed by 2D gel electrophoresis as in Fig. 2 except that in *c*, *d* and *e* non-gradient 12.5% gels were used for the second dimension. Radioactive proteins were detected by fluorography. *a*, *c*, Control cells; *b*, *d*, cells treated with 500 U ml<sup>-1</sup> interferon for 7.5 h. *e*, cells treated with 500 U ml<sup>-1</sup> interferon and 2 µg ml<sup>-1</sup> actinomycin D for 7.5 h. The pH gradient in the isoelectric focusing gel was measured with a Bio-Rad propHiler and the equivalence of pH and the cm scale is shown. The shallow pH gradient at the basic end of the gel has been noted previously by O'Farrell<sup>17</sup>. Parts *a*, *b* were from the same experiment as Fig. 2, and *c*, *d* and *e* from another. In *c*, *d* and *e* only the region of the gel containing the induced protein is shown. The vertical scale in *a*, *b* shows the positions to which standard proteins (molecular weights in kilodaltons) migrated on the gel.

(500 U ml<sup>-1</sup>) for 7.5 h and then incubated with <sup>35</sup>S-labelled amino acids for 1 h. The labelled proteins from the cells were analysed by 2D gel electrophoresis and the pattern of radioactive proteins was compared with that derived from similarly labelled control cells (Fig. 3a, b). The interferon-treated cells show strongly increased labelling of a protein which has the same mobility as the protein observed in Fig. 2 to be present in increased amounts in the translation products of the mRNA from interferon-treated cells. There are other proteins on the 2D gels whose labelling sometimes seems to be affected *in vivo* by interferon treatment but we have not fully established conditions for the changes in labelling of these proteins or found any changes in the corresponding mRNA levels. If cells are treated as above with interferon (Fig. 3d) except that actinomycin D is added at the same time as the interferon (Fig. 3e), the labelling of the 14,500-MW protein is the same as in the control cells (Fig. 3c). When cells are treated with interferon for various lengths of time then incubated with radioactive amino acids and analysed as above on 2D gels, the induction can just be observed after 5 h of interferon treatment and seems to be maximal by 9 h of interferon treatment (data not shown).

We scanned the spots on the fluorograms of the 2D gels and compared the relative blackening on the films to obtain an approximate estimate of the degree of induction of the 14,500-MW protein. This results in values of 7.5-fold for the labelled cells and five-fold for the *in vitro* translations.

We have not yet been able to equate this induced protein with any of the enzymes known to increase in activity after interferon treatment. We have not found any difference in double-stranded RNA-dependent protein kinase activity<sup>6-8</sup> in the translation products of the mRNA from control and interferon-treated cells (data not shown). Nor do we detect any difference in the ability of the translation products to synthesise the 2,5A class of compounds<sup>9</sup>. The 14,500-MW protein does not appear to be mouse globin (determined by co-electrophoresis) or interferon (assayed by antiviral activity). As 500 U ml<sup>-1</sup> interferon slows the growth of these cells by less than 5% in the first 5 days of treatment, it seems unlikely that the induction we have observed is an indirect consequence of an inhibition of cell growth by interferon. We presume that our induced protein is different from a 56,000-MW protein recently reported by Ball<sup>10</sup> to be induced in chick cells by interferon and we are currently trying to establish the function of the induced 14,500-MW protein and to examine other cell types for similar phenomena.

Interferon was purified by H. Taira and R.J.B. This work was supported by NIH grants (AI-12320 and CA-16038) and a fellowship grant (DRG-189-FT) to P.J.F. from the Damon Runyon-Walter Winchell Cancer Fund.

## Hydroxylamine stimulates carboxylase activity and inhibits oxygenase activity of cyanobacterial RuBP carboxylase/oxygenase

RIBULOSE-1,5-BISPHOSPHATE (RuBP) carboxylase/oxygenase (EC 4.1.1.39) catalyses both the photofixation of CO<sub>2</sub> and light-dependent O<sub>2</sub> uptake (photorespiration) in photo-trophs<sup>1-4</sup>. Photorespiration is generally considered to be a wasteful process, reducing net plant productivity<sup>5,6</sup> and N<sub>2</sub> fixation where it occurs<sup>7</sup>. The selective inhibition of RuBP oxygenase activity, either by endogenous metabolites or exogenous effectors, while allowing carboxylation to continue, has been viewed as a means of increasing plant productivity<sup>5,6</sup>. There is no previous unequivocal evidence of one metabolite differentially affecting both reactions. Here, we present data on how it is possible, *in vitro*, to stimulate carboxylase activity and inhibit oxygenase activity simultaneously in extracts of the cyanobacterium *Anabaena cylindrica* by adding hydroxylamine, an intermediate in the reduction of nitrate to ammonia in cyanobacteria<sup>8</sup> and higher plants<sup>9</sup>.

*Anabaena cylindrica* Lemm. (1403/2a) (Culture Centre of Algae and Protozoa, Cambridge, UK) was grown in pure culture as described previously<sup>10</sup>. RuBP carboxylase activity, measured as RuBP-dependent <sup>14</sup>CO<sub>2</sub> incorporation into acid-stable material, and RuBP oxygenase activity, assayed as RuBP-dependent O<sub>2</sub> consumption, were followed simultaneously in an O<sub>2</sub> electrode. Preincubation for 10 min at between 0 and 40 °C had no effect on either RuBP carboxylase or oxygenase activities subsequently assayed at 30 °C. However, a 60% increase in both activities of the enzyme occurred after incubation at 50 °C for 10 min, before assay at 30 °C. The ratio of oxygenase/carboxylase activity remained fairly constant at around 0.063, irrespective of the temperature within the range 0-50 °C. This is the first evidence of heat activation of the enzyme from a cyanobacterium and accords with the finding of heat activation of the eukaryotic enzyme<sup>11-14</sup>. Experiments detailed below were carried out after pretreatment of the *A. cylindrica* enzyme at 50 °C for 10 min, followed by equilibration at 30 °C for 2 min.

**Table 1** Effects of various nitrogen compounds on the RuBP carboxylase/oxygenase activities of *Anabaena cylindrica*

Nitrogen compound added	RuBP carboxylase		RuBP oxygenase	
	1.25 mM*	10 mM*	1.25 mM*	10 mM*
None	100	100	100	100
KNO <sub>3</sub>	102	101	93	86
KNO <sub>2</sub>	82	88	72	79
NH <sub>2</sub> OH	NT	171	NT	72
NH <sub>4</sub> Cl	94	101	89	95

The preincubation temperature was 50 °C and the assays were carried out in the presence of 0.14 mM RuBP; other experimental details as in legend to Fig. 1. Activities are expressed as a percentage of those measured in the absence of nitrogen compounds.

\* Final concentration of added nitrogen compound; NT, not tested.

Data on the effect of various nitrogen compounds on RuBP carboxylase/oxygenase activities (Table 1) show that of the compounds tested only hydroxylamine had any significant effect, stimulating carboxylase activity markedly and inhibiting oxygenase activity. Figure 1 shows the differential effects of hydroxylamine on *A. cylindrica* RuBP carboxylase and oxygenase activities at various effector concentrations. RuBP oxygenase was again inhibited by hydroxylamine, while carboxylase

was simultaneously enhanced when the hydroxylamine concentration was increased up to 10 mM. The differential effect of hydroxylamine on these reactions was greater in the presence of 0.14 mM RuBP than at 0.28 mM RuBP.

Our findings with hydroxylamine show similarities to and differences from the results of Bhagwat *et al.*<sup>15</sup> using the spinach enzyme. Like them, we found an inhibition of RuBP oxygenase activity by hydroxylamine, but also, unlike them, we found a stimulation of RuBP carboxylase activity by hydroxylamine. Although this may reflect a difference between the prokaryotic and higher plant enzyme, it could also be due to the assay methods used. In particular, the Indian workers<sup>15</sup> used separate

**Fig. 1** Effects of increasing hydroxylamine concentrations on *Anabaena cylindrica* RuBP carboxylase/oxygenase activities at two RuBP concentrations. 8 l of log phase culture were collected by centrifugation, washed and resuspended in 2 vol. buffer (20 mM Tris, 1 mM Na<sub>2</sub>EDTA, 10 mM MgCl<sub>2</sub>, 50 mM NaHCO<sub>3</sub>, 0.5 mM dithiothreitol and 1 mM phenylmethylsulphonyl fluoride, pH 8.0). Cells were disrupted by French pressure cell treatment at 110 MPa at 4 °C. The extract was then centrifuged at 15,000g for 20 min and the supernatant re-centrifuged at 100,000g for 60 min. After (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> precipitation of the supernatant, the 25–45% fraction was resuspended in buffer and concentrated by dialysis against buffer. This served as the enzyme preparation. Heat activation was carried out on 125-μl samples of enzyme in 1.5-ml capped vials to prevent loss of CO<sub>2</sub>. The vials were incubated at 50 °C for 10 min, then maintained at 30 °C, the assay temperature, for 2 min before assay. RuBP carboxylase and oxygenase activities were measured simultaneously using a Pt-Ag oxygen electrode (Rank). Assays were started by adding 50 μl enzyme (10–40 μg protein) to the reaction mixture containing 100 mM Bicine-NaOH buffer, pH 8.3 (equilibrated with CO<sub>2</sub>-free air), 0.27 mM NaH<sup>14</sup>CO<sub>3</sub>, 20 mM MgCl<sub>2</sub> and 0.14 mM or 0.28 mM RuBP. In the final assay concentrations produced (21% O<sub>2</sub>, 2.56 mM NaHCO<sub>3</sub> at pH 8.3) carboxylase and oxygenase activities were simultaneously followed. Oxygen uptake was linear for at least the first 100 s and data presented are those obtained over this 100-s period. Carboxylase activity was determined, after 100 s, by removing a 100-μl aliquot of the reaction mixture into trichloroacetic acid (final concentration 40% w/v). <sup>14</sup>C incorporated into acid-stable material was then counted. Controls without RuBP were included. *a*, 0.14 mM RuBP; *b*, 0.28 mM RuBP; ▲, RuBP carboxylase; ●, RuBP oxygenase. Activities are expressed as a percentage of those measured minus hydroxylamine. Specific activities, measured minus hydroxylamine were: RuBP carboxylase, 8.13 and 12.13 μmol CO<sub>2</sub> fixed per mg protein per h at 0.14 and 0.28 mM RuBP respectively, and RuBP oxygenase, 0.88 and 0.90 μmol O<sub>2</sub> consumed per mg protein per h at 0.14 and 0.28 mM RuBP respectively.

**Fig. 2** Possible interactions between hydroxylamine and RuBP carboxylase/oxygenase based on our *in vitro* data. Solid lines represent metabolic pathways, broken lines represent inhibition (–) or activation (+) of enzymatic activities. PGA, 3-phosphoglyceric acid.

RuBP carboxylase and oxygenase assays and saturating bicarbonate and O<sub>2</sub> concentrations, starting both reactions by the addition of RuBP. We measured RuBP carboxylase and oxygenase activities simultaneously in the same vessel using assays with sub-optimal concentrations of CO<sub>2</sub> and O<sub>2</sub> respectively, and started the reactions by the addition of heat-activated enzyme. The effect of hydroxylamine on RuBP carboxylase may depend on CO<sub>2</sub> concentration, as well as on RuBP concentration. It has also been suggested that high CO<sub>2</sub> concentrations may protect the spinach RuBP carboxylase<sup>15</sup> and our data support this contention.

The results point to a possible close coordination of nitrogen and carbon metabolism in *Anabaena*, as Solomonson and Spehar have postulated for *Chlorella*<sup>16</sup>. The latter workers suggest that hydroxylamine, produced during nitrate assimilation, combines with glyoxylate, produced by glycollate oxidation, to form glyoxylate oxime, and thence cyanide. Cyanide, produced in photorespiratory conditions, may thus effect the reversible inhibition of nitrate reductase at low concentrations. However, although cyanide production by *Chlorella vulgaris* has been demonstrated<sup>17</sup> and cyanide inhibits *Chlorella variegata* nitrate reductase *in vitro*<sup>18</sup>, this inhibition does not occur when nitrate is present (see Table 4 of ref. 18). The inhibition of RuBP oxygenase by hydroxylamine would serve to reduce photorespiratory glyoxylate production and, according to the model of Solomonson and Spehar<sup>16</sup>, cyanide production. Our data, showing the direct inhibition of RuBP oxygenase by hydroxylamine, suggest that a regulation of photorespiratory carbon flow and nitrate assimilation may occur without the involvement of cyanide.

*In vivo*, the provision of adequate carbon skeletons is essential to prevent uncoupling by high pools of ammonia (Y. Steinitz, G.A.C. and W.D.P.S. in preparation). Our data suggest that in the presence of nitrate, hydroxylamine may contribute to the fine coordinate control of ammonia levels and the supply of carbon skeletons, as outlined in Fig. 2. The stimulatory effect of hydroxylamine on RuBP carboxylase and its concomitant inhibition of photorespiration would increase net carbon gain, thus helping to ensure the adequate supply of carbon skeletons for amino acid biosynthesis. The *in vivo* significance of these findings will depend on the size of the intracellular pools of hydroxylamine, or if hydroxylamine remains enzyme bound<sup>19</sup>, on an association between RuBP carboxylase/oxygenase and nitrate/nitrite reductase(s), or both. There is no evidence yet for a close association of such enzymes in cyanobacteria but there is evidence for such an association in eukaryotic systems<sup>20–22</sup>.

It is also known that nitrate stimulates O<sub>2</sub> evolution when supplied to algae incubated in CO<sub>2</sub>-limited conditions and this

has been attributed to nitrate acting as an alternative electron acceptor to CO<sub>2</sub> (ref. 23). Our data suggest that if hydroxylamine inhibits RuBP oxygenase activity *in vivo* this would decrease O<sub>2</sub> uptake and be responsible, in part at least, for the enhancement of O<sub>2</sub> evolution.

Irrespective of their *in vivo* significance, our data establish the fact that the RuBP carboxylase/oxygenase from an oxygenic photosynthetic prokaryote can be differentially regulated by chemical means.

## Nitrogen fixation in coral reef sponges with symbiotic cyanobacteria

NITROGEN FIXATION by endosymbiotic cyanobacteria (blue-green algae) results in an important input of nitrogen into terrestrial ecosystems<sup>1</sup>; however, there is as yet little information on its significance in the marine environment<sup>2,3</sup>. Symbiosis of cyanobacteria with marine animals, although rare, is known to occur in an echiuroid worm<sup>4</sup> and in sponges from coral reefs<sup>5</sup> and the Mediterranean<sup>6</sup>. In the present study of sponge–cyanobacterial symbioses, several sponges from a coral reef in the Red Sea were tested, using the acetylene reduction technique<sup>7</sup>, immediately after their collection on reef-based platforms for their ability to fix nitrogen. Nitrogenase activity was detected in two sponges with cyanobacteria but not in a third with no cyanobacteria. This is the first demonstration of nitrogenase activity in an animal with symbiotic cyanobacteria. In two previous reports of nitrogen fixation in marine animals, the activity was attributed to bacteria in the gut<sup>8,9</sup>. Although these preliminary experiments are not sufficient to assess the significance of cyanobacterial nitrogenase activity in sponges, it is possible that any additional fixed nitrogen would be beneficial

to sponges in tropical waters which are low in available nitrogen<sup>10</sup> and in particulate nutrients<sup>11,12</sup>.

Three sponges, two containing cyanobacteria and one without, were collected from illuminated habitats at a depth of 6–7 m on Harvey Reef adjacent to Port Sudan. The consistent presence of unicellular cyanobacteria, similar to those observed in other coral reef sponges<sup>5</sup>, was confirmed by electron microscopy. The cyanobacteria were observed, along with other bacteria, in large vacuolated cells, termed bacteriocytes<sup>13</sup>, throughout the tissue of *Siphonochalina tabernacula* (Row) (Fig. 1). The cyanobacteria were present in low numbers and are estimated to occupy less than 1% of the sponge volume seen in the electron micrographs. Similar cyanobacteria were observed in the thin brown pigmented ectosome of *Theonella swinhoei* Gray where they constitute 10–15% of the ectosome volume. These cyanobacteria are mostly free in the intercellular matrix with some present in specialised amoebocytes, termed cyanocytes<sup>5</sup>. Cyanobacteria numbers decrease away from the ectosome and are not evident in the deeper part of the endosome. Symbiotic bacteria are rare in the ectosome and particularly numerous in the endosome. Large populations of bacteria are the only symbionts observed in *Inodes erecta* (Keller).

Nitrogenase activity was determined using the acetylene reduction test as modified by Flett *et al.*<sup>14</sup>, except that the acetylene gas phase was maintained over the liquid phase because the sponge tissue was too fragile to agitate. Tissue samples were suspended in filtered seawater and incubated in 100-ml glass syringes at a depth of 30 cm in seawater exposed to saturating illumination (full sunlight,  $5 \times 10^{16}$  quanta cm<sup>-2</sup> s<sup>-1</sup>) and at temperatures 1–4 °C above the ambient 31 °C. Duplicate 5-ml gas samples were collected in pre-evacuated tubes ('vacutainers') and estimated for ethylene content by gas chromatography at laboratories in the University of Bristol and Westfield College, London. After correcting for initial contamination, the ethylene concentration was determined using a variation of Henry's law<sup>14</sup>.

When similarly sized pieces of *S. tabernacula* and *I. erecta*, collected from similar habitats, were incubated with acetylene, ethylene was produced in *S. tabernacula* and apparently consumed in *I. erecta* (Fig. 2a). Adjacent pieces from a large *S. tabernacula* specimen were incubated in light or dark, with considerably more ethylene being produced in the light sample (Fig. 2b). The rate of production of ethylene in *S. tabernacula* was linear during the initial 2 h of incubation, with rates slightly decreasing in the subsequent period (Fig. 2c). In similarly sized tissue pieces of *S. tabernacula* incubated in the light with DCMU (dichlorophenyl dimethyl-urea), a specific inhibitor of photosystem II reaction having no effect on animal tissue, no appreciable reduction in total ethylene production was observed during the incubation period (Fig. 2c). The presence of DCMU had an apparently stimulatory effect on the O<sub>2</sub>-sensitive nitrogenase by depressing photosynthetic O<sub>2</sub> evolution, although this effect was probably compensated for later by the shortage of photosynthetically produced reductant<sup>15</sup>. In both dark and DCMU treatments, nitrogenase activity in the cyanobacteria may have persisted at the expense of preformed or non-photosynthetic source of reductant<sup>16</sup>, or activity could have been partly or fully bacterial in origin. In *T. swinhoei*, ethylene production in tissue samples containing between 20% and 30% pigmented ectosome was higher than in the non-pigmented endosome (Fig. 2d).

Nitrogenase activity is thought to be associated with the symbiotic cyanobacteria rather than other bacteria, for the following reasons: (1) nitrogenase activity was evident in *S. tabernacula* and *T. swinhoei*, which harbour symbiotic cyanobacteria, and was absent in *I. erecta*, which lacks cyanobacteria; (2) more ethylene was produced by the ectosome of *T. swinhoei*, which contained cyanobacteria, than by the endosome almost free of cyanobacteria; (3) nitrogenase activity was higher in illuminated tissue than in tissue incubated in the dark; and (4) the amounts of ethylene produced in *S. tabernacula* and

**Fig. 1** *a*, Electron micrograph showing cyanobacteria (C) and bacteria (B) within sponge cell vacuoles in the intercellular matrix of *Siphonochalina tabernacula*. Tissue was fixed in 2.5% glutaraldehyde in seawater:water (4:1), post-fixed in 1%  $\text{OsO}_4$  and embedded in Spurr's resin.  $\times 30,000$ . *b*, Section through sponge vacuole showing cyanobacterium with spiral thylakoid and adjacent smaller bacteria.  $\times 15,000$ .

*T. swinhoei* were comparable although the bacterial population in *T. swinhoei* was many times larger than that in *S. tabernacula* and similar to that in *I. erecta*.

It is unlikely that nitrogenase activity was due to exogenous microorganisms colonising the surface, as the sponge epithelial cells (exo- and endopinacocytes) readily phagocytose particulate matter adhering to the surface<sup>12</sup>.

Although we conclude that the nitrogenase activity measured was due mainly or solely to symbiotic cyanobacteria, the role of other bacterial symbionts must be considered. Mixed populations of bacteria occur in sponges<sup>5,13</sup>, including phototrophic anaerobes<sup>17</sup>, and it is possible that some of these bacteria display nitrogenase activity. Associations between aquatic cyanobacteria and heterotrophic bacteria were considered to be beneficial to both partners<sup>18</sup>. Bacteria possibly enhance nitrogen fixation in freshwater cyanobacteria by creating a reducing atmosphere<sup>19</sup>. Synergistic nitrogen fixation may occur in sponges when cyanobacteria and heterotrophic bacteria are closely associated (Fig. 1).

More detailed experiments are required to establish the nutritional and ecological significance of the nitrogenase activity determined in these preliminary experiments. Although at first sight the levels of activity, 2–4 nmol  $\text{C}_2\text{H}_4$  produced per g (wet weight of sponge) per h for *S. tabernacula* and 3 nmol  $\text{C}_2\text{H}_4$  per g per h for *T. swinhoei*, seem to be rather low, it should be remembered that they originate from small populations of cyanobacteria in a tissue containing large quantities of intercellular matrix and inert skeleton. Comparisons with data obtained with other systems are not possible until the cyanobacterial population may be reliably estimated, and the cyanobacteria isolated and tested in pure culture.

We thank Professors G. E. Fogg and D. C. Smith for their critical comments during the preparation of this manuscript, and

## Antiviral antibody reacting on the plasma membrane alters measles virus expression inside the cell

SOME viruses are known to persist despite a functional antiviral immune response by the host. For example, measles or measles-like viruses can cause persistent infection in man leading to a progressive degenerative disease, subacute sclerosing panencephalitis (SSPE), characterised by unusually high titres of measles virus antibodies in serum and cerebral spinal fluids (see refs 1, 2 for reviews). Peripheral blood lymphocytes specifically responsive to measles virus antigens are generated and lyse target cells expressing virus antigens on their surfaces<sup>3,4</sup>. Sera from SSPE patients enhance rather than block or suppress immunologically mediated killing<sup>3–5</sup>. But although this anti-measles virus immune response is vigorous, the virus infection does not terminate because one can detect virus antigens and isolate infectious virus from central nervous system and lymphoid tissues<sup>1</sup>. To explain this we postulated that antibody to measles virus modulates or strips viral antigens off surfaces of virus infected cells<sup>6–7</sup>. This contention is based on the finding that specific measles antibody added to cultured infected cells modulate viral antigens on the cells' surfaces<sup>6</sup>. These cells then express less viral antigens on their surfaces and thereby avoid the host's immune assault. Cells denuded of viral antigens on their surfaces resist antibody and complement-mediated or immune lymphocyte-mediated killing<sup>6,7</sup> yet retain viral genetic information<sup>6</sup>. Further, during antibody modulation *in vitro*, the numbers of viral nucleocapsids accumulated inside the cell dramatically increase and are positioned randomly<sup>6</sup>. This *in vitro* picture closely resembles the distribution of nucleocapsids in cells obtained by biopsy from patients with SSPE<sup>1,8,9</sup>. Quantitatively, about 10- to 50-fold less antibody is needed on the surfaces of infected cells to modulate viral antigens than is needed to activate the complement system leading to immune lysis of infected cells<sup>5,10</sup>. To clarify the molecular events occurring during antibody-induced antigenic modulation, we have

studied measles virus antibody bound to the surfaces of infected cells and ascertained what alterations occur within these cells. Here we report that measles virus antibodies added to virus infected HeLa cells decrease the content of both viral structural polypeptide haemolysin expressed on the cell surface and a structural polypeptide (measles virus phosphoprotein, P) found inside the cell. These observations indicate that antibody directed against an antigen on the cell surface can interfere with viral proteins expressed inside the cell. Because phosphoprotein seems to form complexes with the nucleocapsid, our findings may offer leads towards understanding viral regulation during persistence. We also note that three measles virus polypeptides—P, nucleocapsid (NC) and matrix protein (M)—are phosphorylated.

HeLa cells acutely infected with measles virus were cultured with and without antibody to measles virus in the media (see Fig. 1 for experimental details). The antibody used for modulation reacted with all measles virus structural proteins as determined by immune precipitation and analysis on polyacrylamide gel electrophoresis (PAGE). The antibody neutralised  $4.5 \times 10^5$  PFU per ml. After being cultured in antibody for 6 or 18 h<sup>6</sup>, HeLa cells were collected, washed four times in serum-free medium, and incubated in media free of either methionine or phosphorus. After 1 h the cells were washed and incubated in methionine- or phosphorus-free media to which <sup>35</sup>S-methionine or <sup>32</sup>P was added. Cells were collected 2 h later from both the controls (infected-unmodulated: NMOD) and the infected modulated (MOD) cultures, washed and lysed with 2% NP40 in TNE buffer. Nuclei and cell debris were removed by centrifugation and the cytosol preparations were incubated with

**Fig. 1** HeLa cells were infected in suspension with Edmonston strain of measles virus at a multiplicity of infection of 1. Cells were pelleted 24 h later and resuspended in Eagle's minimal essential media (MEM) containing either fetal calf serum (FCS) (non-modulated, NMOD) or antibodies to measles virus (modulated, MOD) for 1 h. The cells were pelleted and suspended in fresh MEM with 20% serum containing antibodies to measles virus or 20% FCS and placed on a rotating platform at 37 °C. At 6 h and 18 h, cells were collected by low-speed centrifugation, washed four times with serum-free MEM and incubated in methionine-free media. After 1 h in which  $10 \mu\text{Ci } ^{35}\text{S}$ -methionine per ml was added and the cells incubated at 37 °C, the cells were washed once with phosphate-buffered saline and lysed at 4 °C with NP40 in TNE buffer containing 1 mM PMSF. Nuclei and cell debris were removed 15 min later by centrifugation at 1,000g for 15 min, and the cytosols (300  $\mu\text{l}$ ) were precipitated with 10  $\mu\text{l}$  hyperimmune antibody to measles virus. Incubation lasted overnight at 4 °C. Thereafter, an excess of heat-inactivated, formalin-fixed *Staph. aureus* was added to precipitate all the formed complexes. Precipitates were washed twice in 0.5% NP40 in TNE buffer and twice again with 0.02% NP40 in buffer, suspended in sample preparation buffer containing 1% SDS and 1% 2-mercaptoethanol and immersed in boiling water for 2 min. The bacteria were pelleted at 1,000g for 15 min and supernatants removed. The immune precipitates were counted and applied to 10.5% SDS gels for PAGE analysis. Gels were stained, fixed and dried on filter paper. Kodak XRP-1 X-ray film was exposed to the dried gels and developed. Appropriate molecular weight markers were run in adjacent lanes.

Data shown are representative of seven such experiments.

**Fig. 2** HeLa cells infected with measles virus were treated as described in Fig. 1 except that phosphorous-free media and  $^{32}\text{P}$  ( $50 \mu\text{Ci ml}^{-1}$ ) replaced the  $^{35}\text{S}$ -methionine and cells were collected 12 h post-infection. The ordinate represent relative density and the abscissa the relative migration. The three phosphorylated measles virus polypeptides seen are: phosphoprotein (P); nucleocapsid (NC) and matrix protein (M). Solid line,  $^{32}\text{P}$  non-modulated; broken line,  $^{32}\text{P}$  modulated.

antibodies to measles virus overnight at  $4^\circ\text{C}$ . The antibody used for immune precipitation recognised all structural measles virus polypeptides found in the virion and in infected cells. The antigen-antibody complexes formed were then precipitated with *Staphylococcus aureus*, washed, dissolved in 1% SDS and 1% 2-mercaptoethanol and electrophoresed on SDS-PAGE in conditions designed to segregate measles virus polypeptides. In the conditions used, structural measles virus polypeptides were immunoprecipitated and co-migrated with purified measles virion polypeptides. Measles virus polypeptides were identified by tryptic peptide mapping<sup>11</sup>. Experimental controls showed that (1) measles virus antibody did not precipitate proteins in uninfected cells that migrated in positions of measles virus polypeptides and (2) sera free of antibodies to measles virus did not precipitate measles virus polypeptides found in infected cells.

Figure 1 shows the five structural polypeptides of measles virus demonstrated when HeLa cells were incubated only in fetal calf serum (NMOD) but not antibody. These are the haemagglutinin (HA), the phosphoprotein (P), the nucleocapsid (NC), the haemolysin (HL) and the matrix protein (M). Only the HA and HL were expressed on the cells' surfaces as detected by lactoperoxidase  $^{125}\text{I}$ -labelling of living cells<sup>12</sup> and previous observations<sup>13</sup>. In contrast, HeLa cells incubated with antibody to measles virus synthesised equivalent amounts of three of the five proteins, namely HA, NC and M as studied with  $^{35}\text{S}$ -methionine label (Fig. 1). Hence, in the experimental conditions used, modulation for 18 h or less, detectable amounts of HL, a surface protein, were markedly diminished by the presence of anti-measles antibody, whereas the other surface protein, HA, was unchanged. In addition, cytosol preparations from antibody modulated infected cells contained less P protein than unmodulated cultures. These results were reproducible and quantitated by both densitometer scans and counting the radioactivity contained within the labelled viral polypeptide. HL decreased by 70% or more and P by 80% or more in the preparations from modulated cells compared to those that were not modulated by antibody. Quantities of NC in modulated and unmodulated cells varied less than 10%. We performed a series of experiments in which the conditions of electrophoresis were altered (7–15% gels with and without urea), several human and rabbit sera containing measles antibody were used to modulate or precipitate, and purified IgG from these human and rabbit sera were used. All gave results similar to those shown in Fig. 1. Failure to decrease the amount of HA expressed on the surfaces of infected cells was unexpected, and probably due to the brief time (<18 h) for which infected cells were modulated. Previous experiments<sup>7</sup> showed that after 48 h of antibody-induced modulation, viral antigens were no longer detected on the cells' surface by either radiolabelled binding or immune cytotoxicity assays. When IgG from sera without antibody to measles virus was added to the cultures in identical conditions, neither HL or P protein were altered in concentration.

We next determined whether antibody(s) to non-viral determinants expressed on the surface of virus-infected cells also decreased the HL and/or P protein of measles virus. For these experiments, measles virus-infected HeLa cells were incubated with antibodies directed to the HeLa cell surface in conditions like those used for modulation. Although antibodies to HeLa cell surface components bound to antigens expressed on the membranes of virus-infected HeLa cells for up to 18 h in culture, the quantitative expression of the five viral polypeptides remained unaltered compared to cultures in which HeLa antibodies were absent or fetal calf serum was substituted. HL reacted correspondingly. Hence, the decreases in P and HL directly reflected the fact that antibodies to measles virus bound to measles virus determinants expressed on the cell surface.

P protein is a phosphorylated protein<sup>14</sup> and we next studied the incorporation of  $^{32}\text{P}$  into this protein during antibody modulation. Figure 2 shows a densitometer scan of immune precipitates obtained from cells labelled with  $^{32}\text{P}$  and autoradiographed. In unmodulated cells, P, NC and M polypeptides all incorporated  $^{32}\text{P}$ , indicating that these three measles virus structural proteins are phosphorylated. Comparatively, in modulated cells, only trace amounts of  $^{32}\text{P}$  were incorporated into P polypeptides while an enhancement of  $^{32}\text{P}$  was incorporated by the M protein. No difference in incorporation of  $^{32}\text{P}$  was noted for NCs studied in modulated and unmodulated cells. Labelling studies with  $^{32}\text{P}$  and  $^{35}\text{S}$  studies were run concurrently (Figs 1 and 2). Changes in the phosphorylation of M protein might alter NC recognition and alignment at the plasma membrane, thereby inhibiting viral maturation. Such alterations in phosphorylation could change the migrational characteristics of M protein on PAGE and may explain, in part, the differences in migration of M protein reported by others with SSPE material<sup>15,16</sup>.

Thus our results show that specific antibody can bind to the surface of an infected cell and not only strip off surface viral determinants but also alter viral polypeptide(s) found inside the cell not associated with the plasma membrane. It is not clear whether there is a decrease in synthesis, increase in degradation, or alteration of the P protein structure that would render it non-antigenic or change its mRNA. Nevertheless, it is clear that antibodies to a specific virus determinant on the cell surface can send a signal transmembrally that alters cytoplasmic viral events. Furthermore, the P protein, or its analogue in other viral systems, seems to be associated with the transcriptional complex<sup>17,18</sup>. The sequence of events described here could lead to alterations of measles viral synthesis leading to persistent infection.

## ***In utero* sister chromatid exchange analysis for detection of transplacental mutagens**

FETAL exposure to agents which damage DNA can result in birth anomalies, cancer and inherited abnormalities. In the present report we describe a new approach for the detection of fetal DNA damage through the enumeration of sister chromatid exchanges (SCE) in mouse fetal chromosomes. SCE can be identified as reciprocal exchanges of fluorescent intensities between sister chromatids in metaphase cells which have divided twice in the presence of bromodeoxyuride (BrdU) (Fig. 1). Analysis of SCE has been shown to be a sensitive and reproducible means of detecting chemical mutagens and carcinogens<sup>1-9</sup>.

Differential chromatid staining of metaphase cells from maternal and fetal tissues was achieved when pregnant females were intravenously infused with BrdU for 24 h at gestational days 11, 15 and 19. SCE frequencies were simultaneously studied in fetal cells as well as in maternal bone marrow. Baseline SCE frequencies in fetal cells were generally lower than in maternal cells, ranging from 2.4 to 3.6 SCE per second replication cycle cell, and these values did not change significantly as a function of gestational age (Table 1, Fig. 1b).

To examine *in utero* SCE induction, three known mutagens (cyclophosphamide, CP; mitomycin C, MMC; adriamycin, ADM) were injected into pregnant females on day 13 of gestation (Table 1, Fig. 1a). Drug concentrations were selected which would induce similar levels of SCE for each agent in maternal cells (approximately 20 SCE per cell<sup>10</sup>). These same drug doses resulted in varying levels of SCE induction in fetal cells. Cyclophosphamide administration resulted in similar SCE induction in fetal and maternal cells; MMC resulted in fetal SCE levels which were slightly lower than those in maternal cells, while fetal SCE induction with ADM was only one third that seen in maternal cells (but significantly higher than baseline levels).

The doses of CP and MMC which resulted in a 5–10-fold increase in fetal SCE were well below the teratogenic doses for these drugs<sup>11,12</sup> while ADM, which showed the weakest induction of fetal SCE, is not teratogenic<sup>13</sup>. We therefore suggest that *in utero* SCE analysis should be used in addition to existing assays for screening fetal exposure to mutagens, carcinogens and teratogens which act at the level of DNA damage. *In utero* SCE analysis is relatively simple, rapid,

**Fig. 1** Photomicrographs of mouse fetal chromosomes. *b*, Second replication cycle cell showing baseline level of SCE; *a*, second replication cycle cell showing cyclophosphamide induced level of SCE. Two to four month-old female C57BL/6J mice (Jackson) were mated with male mice of the same age and strain. Gestational age was determined by counting the number of days after observation of vaginal plugs or by examination of fetuses at the time of killing. Pregnant mice were infused according to our previously described techniques at 50 mg per kg wt per h (refs 8, 15). After 23 h of intravenous infusion, mice were injected with 2.5 µg demecolcine (Colcemid, GIBCO) and killed 1 h later. Those mice treated with mutagens (CP, Mead, Johnson; MMC, Sigma; ADM, Adria Labs) were injected intravenously 1 h after the onset of the infusion. After killing, the entire uterus was excised and individual fetuses incubated in 0.2% collagenase (GIBCO). Vigorous pipetting in Eagle's minimal essential medium (MEM) resulted in single cell suspensions of fetal tissues. Cells were isolated from maternal bone marrow as described previously<sup>8,15</sup>. Cell suspensions were then swollen in 0.07 M KCl, fixed (methanol/acetic acid, 3:1) and dropped on to glass slides. Chromosome preparations were stained with 4'-6-diamidino-2-phenylindole (10 µg ml<sup>-1</sup>, (ref. 16)) and chromosomal analyses were performed with a Zeiss photomicroscope equipped with epi-illumination.

reproducible, requires small numbers of animals, allows simultaneous examination of the effect of agents on fetal and maternal cells, and may be more sensitive than previously described techniques such as the micronucleus assay<sup>14</sup> or measurement of chromosomal aberrations<sup>1</sup>.

## The pair of central tubules rotates during ciliary beat in *Paramecium*

UNLIKE the one-dimensional movement of striated muscle, the beat of a cilium is typically three dimensional<sup>1</sup>. Thus, the dynein arms, which are situated on the peripheral tubules around the circumference as well as longitudinally along the cilium, must be temporally coordinated in their actions. The mechanism for coordination is not known. The present study was undertaken to see whether the pair of central microtubules exhibits any systematic movement during the ciliary beat. We conclude that the central pair of tubules rotates anticlockwise 360° per beat cycle and that this rotation may regulate the dynein arms. *Paramecium* cilia were used because: markers distinguish the two central tubules so that their orientation can be unambiguously determined; and the metachronal waves of cilia can be 'instantaneously fixed' for the analysis of sequential phases of the beat.

The force required for motion of cilia, eukaryotic flagella and sperm tails is generated by the dynein arms, which cause sliding of adjacent peripheral microtubule doublets<sup>2-4</sup>. The dynein arms have been shown to contain  $Mg^{2+}$ -ATPases<sup>5</sup>. The force generated by the arms can only cause the adjacent doublets to move tipward<sup>6</sup>. As the dynein arms are arranged in a ninefold radial symmetry, a force generated on one side will be cancelled by that on the opposite side. Thus, the physical arrangement necessitates a regulatory mechanism that allows some of the dynein arms to work while others do not. The central pair of the 9+2 microtubular structure is a candidate for at least part of this regulatory mechanism for several reasons. First, orientation of the central pair is correlated with beat direction. The central pair is orientated at right angles to the power stroke in a wide variety of metazoan cilia<sup>7,8</sup>. Gibbons<sup>8</sup> noted that in the Protozoa *Paramecium* and *Opalina*, the central-pair orientation was not uniform. Tamm and Horridge<sup>9</sup> then showed that the orientation of the central pair was perpendicular to the direction of bending, even when the effective stroke direction was changed. Second, various *Chlamydomonas* mutants missing one or both of the central tubules or even some accessory components of the central-tubule complex are found to be paralysed<sup>10</sup>. In these mutants, the dynein function, as assayed by peripheral microtubule sliding, remains normal<sup>11</sup>. Third, studies have indicated some interactions between the radial spoke of the peripheral doublets and the projections from the central pair. It has been suggested that such interactions convert sliding to bending<sup>12</sup>. When the radial spokes are deleted by mutations, the cilia are also paralysed<sup>11,26</sup>.

As in *Tetrahymena*<sup>13</sup>, the two central tubules in *Paramecium* can be distinguished by a 20-nm spur on one tubule (Fig. 1a). The two central tubules also terminate at different levels near the ciliary base (Fig. 1b), as shown by Dute and Kung<sup>14</sup>. Using both of these morphological markers, we have examined the orientations of central pairs near the bases of cilia on serial sections of the *Paramecium* surface. We have examined 119 central pairs in which both the insertion into the axosome and the 20-nm spur could be scored. A vast majority of these, 108 central pairs, show that the tubule which is inserted into the axosome also bears the spur (Fig. 1a, b). Of the remaining 11 cases, eight are ambiguous because different tubules were scored to have the spur in different serial sections. Only three cases show that the tubule with the spur is not inserted into the axosome. This observation makes the recent speculation by Hausmann and Fischer-Defoy<sup>21</sup> that there is alternate sliding of central tubules unlikely, and also increases our confidence in tubule identification. Using the spur and/or the axosomal insertion as markers, a vector can be drawn from the tubule without a marker to the tubule with the marker(s). The angular changes of this vector can then be studied.

**Fig. 1** a, Cross-section of a *Paramecium* cilium showing the 20-nm spur (arrow),  $\times 44,850$ . b, The same cilium as in a in more proximal section showing the tubule with the spur entering the axosome. The axosome is seen as an electron dense material around the tubule in cross-section,  $\times 44,850$ . c, Scanning electron micrograph of an instantaneously fixed *Paramecium* showing metachronal waves (arrows),  $\times 552$ . Wild-type *Paramecium tetraurelia*, 51s, were grown in Cerophyl medium bacterised with *Enterobacter aerogenes*<sup>15</sup>. The cells were washed then fixed while swimming in 4 mM  $CaCl_2$ , 1 mM Tris-HCl pH 7.2. An excess of instantaneous fixation solution (S. L. Tamm, personal communication) with final concentration of 2%  $OsO_4$ , 2% glutaraldehyde, 0.05 M Na-K phosphate pH 7.2 was pipetted on to cells and left at room temperature for 10–15 min. The cells were washed, post-fixed in 0.5% uranyl acetate and dehydrated through ethanol series. For scanning electron microscopy the cells were critical-point dried in 20- $\mu$ m mesh Nitex bags, put on stubs, coated with carbon-platinum and viewed on a JSMU3 scanning electron microscope. For transmission electron microscopy, cells were embedded in Epon-araldite<sup>16</sup> or in Spurr's<sup>17</sup> and sectioned on a Reichert OmU3 ultramicrotome. The sections were stained either with 0.5% uranyl magnesium acetate then lead citrate<sup>18</sup> or 1% potassium permanganate<sup>19</sup> then lead citrate<sup>20</sup>. Serial sections were photographed on a Phillips 300 electron microscope then enlarged photographically before examination.

Each beat cycle of the *Paramecium* cilia has a planar power stroke and a three-dimensional recovery stroke<sup>22</sup>. The cilia of an actively swimming *Paramecium* do not all beat in synchrony. Adjacent cilia in certain directions are slightly out of phase so that metachronal waves (Fig. 1c) are propagated. These waves give us an opportunity to study ciliary beat. Cilia at the same phase of beat form a line of synchrony parallel to the direction of the power stroke. Perpendicular to this line of synchrony, and in the direction of wave propagation, cilia are in progressively earlier phases of the beat (Fig. 2). Cilia just before the power stroke are at the wave crests (position 1, Fig. 2). The wave troughs (position 2) are made by cilia at the beginning of their recovery stroke which comprises most of the wave (positions 3–5). In *Paramecia* that have been 'instantaneously fixed', the waves are well preserved with cilia frozen in various phases of their beat (Fig. 1c). Our strategy has been to reconstruct the events during the ciliary beat cycle by examining the ultrastructure and orientation of central pairs of cilia along the line of wave propagation.

To examine the possible angular changes of the vector of the central pair, micrographs of the 20 to 30 serial sections near a *Paramecium* surface were traced, with cross-sections of all cilia outlined. The tubules with the spur and/or axosomal insertion were marked and the vectors drawn. Each cilium was numbered on each of the serial sections and the numbering was maintained through the series. An arbitrary line constant for all sections was

used to measure the angles of the vectors. The measured angles were grouped into nine  $40^\circ$  sectors. The classification of the angles into nine sectors is arbitrary but reflects the impracticability of measuring the angles with greater accuracy. The angle and coordinates for each cilium from all the serial sections were compiled into one map. The angles measured from all the cilia in the sections are not constant but span all the nine possible sectors. The best-fit set of parallel lines through groups of cilia with the same sector angle was drawn using a computerised co-variance analysis. In the more distal sections of the series, cilia could be seen in various cross, glancing or longitudinal views, depending on the phases of their beats. A survey of the pattern of these images of cilia enabled us to estimate the lines of synchrony. We found that the lines of synchrony estimated by this method parallel the lines of best-fit drawn from the angular data.

The orientation of each ciliary central pair near the base is plotted against its distance from a fixed computer-drawn line of synchrony (Fig. 3). Neighbouring cilia with central pairs in the same orientation are grouped (brackets in Fig. 3). In one typical case, shown in Fig. 3, the mean distance between neighbouring central pairs within groups is only  $1.4 \pm 0.7 \mu\text{m}$  (mean  $\pm$  s.d.; range  $0-3.5 \mu\text{m}$ ), while the mean distance between groups of the same orientation is  $6.7 \pm 1.2 \mu\text{m}$  (range  $6-12 \mu\text{m}$ ).

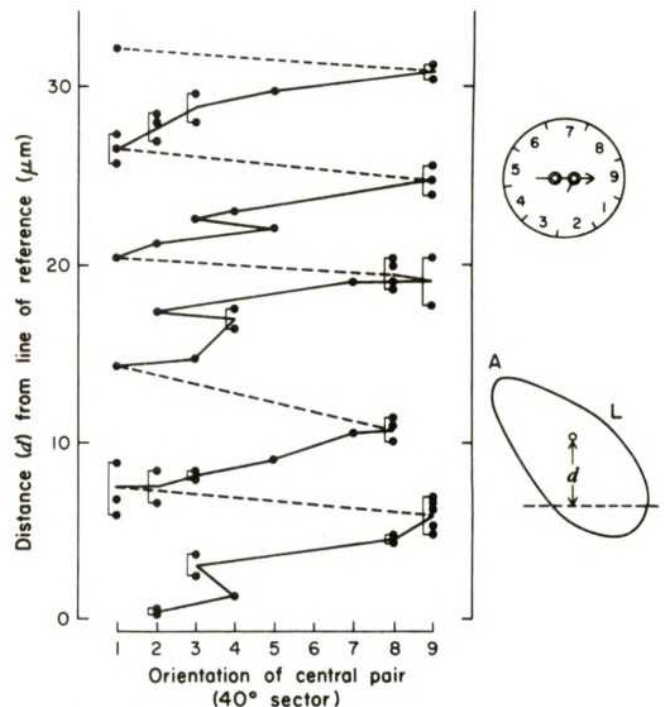

The central-pair orientation of cilia located along the perpendicular of the line of synchrony changes systematically in the anticlockwise direction (looking from tip to base) as one proceeds in the sequence of their beat cycle. This shift in orientation is continuous, with the exception of a few of the cilia in the cell in Fig. 3. The curvature of the *Paramecium* surface, the inaccuracy in aligning serial sections, the inability to score and include the vector for all the cilia and the imperfection of the metachronal waves themselves, all contribute to departure from the ideal.

We can also estimate the approximate wavelengths using the more distal sections described above, where cilia are seen in various views depending on the phases of their beat. In the case shown in Fig. 3, the wavelength is between 7 and  $12 \mu\text{m}$ . This is similar to the distance of  $6.7 \pm 1.2 \mu\text{m}$  (range  $6-12 \mu\text{m}$ ) between cilia having the same central-tubule orientation. Similar results have been obtained in four other *Paramecia*.

In the opposite direction from wave propagation, cilia are frozen at phases of the temporal sequence of their beat (Fig. 2)<sup>22</sup>. For a *Paramecium* fixed during forward swimming, this direction is from its anterior left to posterior right. Along this same direction we see that the central pairs rotate anticlockwise.

**Fig. 2** Stylised diagram of metachronal waves of cilia on the surface of *Paramecium*. Phases of ciliary beat are numbered 1-5. The power stroke is from 1 to 2 and the recovery stroke from 2, 3, 4, 5 back to 1. For a forward-swimming *Paramecium*, the power stroke is from anterior right to posterior left (refer to compass; A, anterior; L, left). This is also the direction of the lines of synchrony (dotted lines), along which cilia are at the same phase of their beat. Perpendicular to these lines of synchrony is the direction of wave propagation (broad arrow) which is opposite the direction of cilia at subsequent phases of their beat.

**Fig. 3** Orientations of the central pairs plotted against the distances of the cilia from a line of reference on the surface of *Paramecium* fixed during forward movement. The line of reference (dotted line of lower inset) parallels the lines of synchrony along which cilia are in the same phase of their beat (see text and Fig. 2). In forward swimming *Paramecium* this line is from its anterior (A) right to posterior left (L). The distances ( $d$ ) are measured in  $\mu\text{m}$ . The orientation of the central pair is represented by a vector drawn from the tubule without a spur to the one with (upper inset). The orientation is classified into nine categories as the vector falls into various  $40^\circ$  sectors. The sectors are numbered clockwise (looking from tip to base) and arranged such that the vector parallels the line of reference at sector 9. Neighbouring cilia with the same central-pair orientation within half a wavelength independently estimated from more distal sections (see text) are grouped (vertical brackets). The line is drawn through cilia or groups of cilia of successively increasing distance ( $d$ ) from the reference line. Note that, in general, the central-pair orientation is successively more clockwise as  $d$  increases. Five complete revolutions are seen. As  $d$  increases in the direction of wave propagation we encounter cilia frozen in successively earlier phases of the ciliary beat in this direction (see text and Fig. 2), and we conclude that the central pair rotates anticlockwise during the beat.

Thus, one simple explanation is that each central pair rotates anticlockwise during the beat. Furthermore, as the wavelength (estimated from distal sections) and the distance between groups of central tubules having the same orientation are similar, one may conclude that there is a  $360^\circ$  rotation with each beat cycle.

As shown in Fig. 3, there are far more central pairs orientated at sectors 8, 9, 1, 2 than at sectors 4, 5, 6, 7. Such an uneven distribution may be related to the temporal asymmetry of the ciliary beat cycle, that is, far more time is spent in the recovery stroke than in the effective stroke. We are now in the process of correlating the orientations of the central pairs to specific phases of the beat cycle.

An alternative interpretation of the data is that the central pair rotates in one direction for several sectors and then quickly rotates back, instead of continuously rotating in one direction. This would explain why few cilia orientate at certain sectors. However, the possibility is unlikely, as, without exception, the central-pair orientation of 27 individual cilia has been found to be progressively more anticlockwise when we examine the progressively more proximal sections of the same cilia. We have also examined  $0.25-0.5 \mu\text{m}$ -thick sections of *Paramecium* cilia under a high-voltage electron microscope and have found twists

in the central pairs. If the rotation of the central pair is generated at the proximal end, a twist may form and propagate distally along the cilium when the pair encounters some resistance along its length.

Regardless of whether the rotation is continuous or discontinuous, these results refer only to the proximal region of the central pairs. As we do not have markers on the peripheral tubules, we cannot determine their movement. Rotation of the whole axonemal assembly within which the central pair is fixed is not likely. Preliminary evidence from thick section high-voltage electron micrographs indicates that the assembly of the nine peripheral tubules also shows twists. However, the twist of the peripheral tubule assembly does not correlate with that of the central pair. Indeed, stereomicrographs of thick sections show that the twist of the central pair is opposite that of the peripheral tubule assembly in some portions of the cilia.

The 360° rotation of the central pair might be unique to a certain class of cilia or, on the other hand, it might be a phenomenon common to many types of cilia with the 9+2 structure. Variation in the orientation of the central pair has been reported. Satir<sup>23</sup> noted differences of more than 90° in the orientation of the central pair in active cilia from *Elliptio* gill fixed instantaneously. In *Opalina* Tamm and Horridge<sup>9</sup> reported that the orientation of the central pair is always at right angles to the direction of bending and that this orientation shifts by almost 90° at the trailing edge of the metachronal wave crests. As neither study used cilia with distinguishable central tubules, the angle variation observed is a minimal estimate.

We propose a model in which the central pair regulates the sliding of peripheral tubules. In this model, the rotation of the central pair acts as a distributor to signal peripheral tubule activity in sequence. This signal may be transmitted to the peripheral doublets through the radial spokes. The rotation of the central pair may generate the twist and cause its helical propagation towards the tip. This model would predict that the period of bend propagation is identical to the period of rotation. Observations with high-speed cinematography by Jarosch and Fuchs<sup>24</sup> of the flagellar motion in *Synura* are consistent with this prediction. This model may also provide the physical basis for the helical propagation of force-generating sites along the cilium postulated by Hiramoto and Baba<sup>25</sup>. The model can be tested by first showing a rotation of the central pair independent of peripheral tubule sliding. This may be done by using cilia whose dynein has been chemically inhibited or genetically removed. The model can be further tested by correlating the central-pair orientation with local dynein ATPase activation or cross-bridge formation.

We thank Drs C. Allen, H. Ris, D. Nelson, Y. Satow, M. Forte, T. Linn, K.-Y. Ling, Y. Saimi, C. Schobert and C. Shusterman for critical reading of the manuscript and Dr Sidney Tamm for use of his laboratory facility at the beginning of this work and help throughout the study. ## Increased incidence of abnormal nasal cilia in patients with retinitis pigmentosa

RETINITIS PIGMENTOSA (RP) is the name given to a group of inherited eye disorders of unknown aetiology, whose symptoms are loss of night vision and constriction of the field of vision. The conditions are progressive and eventually in some cases blindness occurs<sup>1</sup>. Although there are certain syndromes which include RP, for example, the Laurence-Moon-Biedl<sup>1</sup>, or Cockayne's syndrome<sup>2</sup>, in most cases the disease is considered to be localised to the eye. However, a high incidence of deafness has always been associated with RP<sup>1,4</sup> and Massof and Finklestein (personal communication) have found that at least 15% of their cases have inner ear deafness not associated with presbycusis or acoustic trauma. As the outer limbs of photoreceptors are modified cilia<sup>3</sup> and the sensory epithelium of the inner ear is derived from ciliated epithelium, we wondered whether RP might be associated with a more general defect of ciliated structures. Accordingly we examined samples of nasal mucosa from 11 patients with RP and report here an increased incidence of cilia with abnormal axonemal microtubular structures, and also of compound cilia. Although our patient sample was small, it was heterogeneous and our findings may therefore apply to patients of different genetic type. If, as seems plausible, the ciliary abnormalities are related to the disease process in the eye, nasal mucosa would offer an accessible source of human material for the study of basic pathological processes in photoreceptors.

All our patients had been investigated at the Retinal, Genetic, and Electrodiagnostic Clinics of Moorfields Eye Hospital. Six of the cases had been called 'Usher's syndrome' (autosomal recessive RP with deafness<sup>4</sup>) although in some cases the deafness was not profound, or was of very early onset. In two cases, the

**Table 1** Relative numbers of abnormal axonemal patterns in patients and normal controls

Controls (N = 11)			RP patients (N = 11)		
9+2 & 9+0	'Tips'	Others (abnormal)	9+2 & 9+0	'Tips'	Others (abnormal)
254	6	13*	219	3	59*

The absence of the central two singlet microtubules (9+0) implies that the section was made near the base of the cilium, and is not an indication of abnormality. Likewise, sections through the tips of the cilia ('Tips', counted in separate column) show single microtubules symmetrically arranged about part or all of the circumference of the cilium. In the controls, between 0 and 19% of abnormalities were seen in various individuals: in the patients, the range was between 6 and 37%. See Table 2 for statistics.

\* $\chi^2 = 31.77$ , highly significant.

**Fig. 1** Transmission electron micrographs of normal and abnormal axonemes of cilia in transverse section. *n*, Normal 9+2 arrangement. *a-g*, Abnormal arrangements of microtubules, all from RP patients. Scale bar, 0.25  $\mu$ m.

inheritance was autosomal dominant: these patients did not complain of deafness and audiometry has not been carried out. In three patients, the RP seemed to be 'sporadic' and associated with deafness. In one of these deafness was inherited dominantly but the propositus was the only member of the family with RP. On this basis, and considering the nature of the disease in each patient, we classify the cases as eight recessive and three dominant. The 11 controls were reasonably well matched for sex and age. Samples of mucosa were taken from the inferior turbinate of the nose under either local anaesthesia (in RP patients and four of the controls) or general anaesthesia (the remainder of the controls). The tissue was immediately pinned flat on a piece of cork, with the ciliated surface uppermost, and placed in Karnovsky fixative to which 2 mmol of  $MgSO_4$  had been added to improve the visibility of the dynein arms<sup>5</sup>. After overnight fixation, the tissue was washed in buffer and postfixed in osmium tetroxide, followed by block staining with uranyl acetate. Tissue was dehydrated, mounted in 'Araldite' and sectioned. Sections were stained with uranyl acetate and lead citrate, and examined in a Phillips 201 electron microscope.

Electron micrographs of transverse sections of cilia were taken at a final magnification of 65,000–180,000. Only those cilia in which a microtubular pattern was clearly seen were counted. In some cases in which there were few precisely transverse sections of cilia, the gonioscopic stage was used to ensure that circular outlines were obtained.

In normal human material there are few departures from the classic 9+2 arrangement of the axonemal microtubules (Fig. 1, *n*). The abnormalities we saw in the patients' material consist of both increases (Fig. 1, *a* and *b*), decreases (Fig. 1, *c-g*) and irregular arrangements of the doublets (Fig. 1, *a* and *b*). There may also be displacement of the two central singlet microtubules (Fig. 1*f*). In one outline (not shown) we found five single microtubules centrally in the axoneme. Using the most conservative criteria, we find >20% of cilia from our patients to be abnormal, compared to 3% from the controls (Table 1).

**Table 2** Percentage of abnormal axonemal structures

s.e.m.	—	0.32%
<i>g</i> Expected no. of compound cilia in control group	21 (from simple average), 55 (from value of $\bar{X}$ )	13–96 ( $\pm 2$ s.e.m.'s)

For each patient, several micrographs ( $\times 10,800$ ) of ciliated epithelium were examined, of length shown in *a*. The length of that single cell associated with the largest number of transverse sections of cilia *b* was then measured. We counted the number of these cilia *c*. From *a* and *b* we calculate the number of cells in the sample, and hence the number of cilia in the sample *d*. This method overestimates the number of cilia. The total number of compound cilia associated with the entire sample is given in *e*. For each patient we were able to determine the proportion of compound cilia, *f*, and thus obtain the s.e.m., which should be normally distributed. Hence we can make predictions *g* about the number of compound cilia we expect to see in the control group, on the assumption that the differences between the two columns are solely due to sampling. The predictions and the experimental result are so different that we can reject this hypothesis.

Both dominant and recessive cases showed the abnormality (Table 2). One patient with autosomal recessive disease had only 6% abnormal axonemes (and other abnormalities, see below). We do not yet know whether this is a sampling error, or whether recessive RP patients fall into more than one group. Though the mean values given in Table 2 show that normal subjects and patients fall into separate groups, we cannot tell from this preliminary survey what the population ranges may be.

Large structures containing many sets of microtubules were seen in many of our patients. Although the incidence of such compound cilia was low ( $\sim 0.3\%$ ) the appearances were bizarre and striking (Fig. 2).

Compound cilia occur in the olfactory system of some fish<sup>6</sup> and in patients with upper respiratory tract infections and allergies<sup>7</sup> (B.F., in preparation). We have therefore excluded from our sample any control or RP patient who had evidence of such conditions. This reduced the number of the control group to five, three of whose tissue was obtained during the course of operation for deviated nasal septum, and two healthy volunteers. Four of the RP patients were excluded on the same grounds. No compound cilia were seen in the normal material, but 39 were counted in the sections made from the RP patients' mucosa, in five of the seven cases. The Fisher exact probability that this result could occur by chance is very low,  $P=0.026$ . However, there are very few compound cilia, even in our patients, and we have therefore attempted more detailed morphometry, as described in Table 3, which shows that the patients have normal sized ciliated cells, and that the total number of cilia is not reduced. Although the incidence of compound cilia is small, given the length of ciliated epithelium examined, there is only a very small probability that the patients and normal material could be drawn from the same population. In one of the two patients in whom we saw no compound cilia, a large sample was obtained, and, using the data from Table 3, we calculate that we should have seen 10 compound cilia, if the incidence was the same in this patient as in the remainder. It is

thus possible that RP patients do not form a uniform population so far as the incidence of compound cilia is concerned.

Apart from deafness, 10 of our cases of RP have difficulties with balance. In one further case (not reported here) we have found abnormalities of the cilia of the uterine tube. Moreover, in Cockayne's syndrome, there is an unexplained predisposition to respiratory infection which could be due to a ciliary defect<sup>2</sup>. The defects of cilia in our patients may be generalised and the loss of photoreceptors could be due to the same basic cause. However, there is evidence that the pigment epithelium, and not the rods, is defective in some animal retinal dystrophies<sup>8</sup> and perhaps in some patients<sup>9,10</sup>. In this connection it seems possible that RP patients do not form a homogeneous group, and one or other or both of the defects shown in Figs 1 and 2 may be absent. This would be important in efforts to subdivide the group of diseases called retinitis pigmentosa, and to assess the number and frequency of abnormal genes<sup>11,12</sup>. Our results do not show immediately how the abnormality detected could produce RP. The growth of rod disks, or the provision of metabolites for the rod outer segments may be associated with the disposition of microtubules in the narrow ciliary neck. The biochemistry of cilia and outer limbs is strikingly similar in many ways<sup>13-17</sup>; and thus cilia may form a useful model for the inaccessible photoreceptors. Research into RP has been handicapped by the lack of normal human ocular tissue, and the almost complete absence of suitable human pathological material<sup>18</sup>. In contrast, it should be possible to obtain large quantities of normal and abnormal human cilia fairly easily.

**Fig. 2** *a*, Transmission electron micrograph showing longitudinal sections through compound cilia, from a patient with dominantly inherited RP. Scale bar, 1  $\mu$ m. *b*, Transmission electron micrograph of compound cilium in transverse section. Note the 7 microtubular patterns with a 9+2 arrangement. The single axoneme at '11 o'clock' has an additional peripheral microtubule. (RP patient, autosomal recessive inheritance.) Scale bar, 0.25  $\mu$ m.

We would like to thank A.E.S. Richards, who took the biopsies, B. Jay and A. Bird for allowing us to use their patients, Mrs M. Jay and Mrs M. Guest (of the British Retinitis Pigmentosa Society) for their assistance and T. Bull for technical assistance.

*Note added in proof:* We have recently investigated three patients with X-linked disease. All have ~40% abnormal axonemes, but two are females, in whom retinal functional defects are mild<sup>11,12,20</sup>, implying that the degree of abnormality of photoreceptors and cilia is not necessarily the same.

## Membrane fluidity of a fatty acid auxotroph grown with palmitic acid

HOMEOVISCIOUS adaptation, whereby the fatty acid composition and unsaturation of complex lipid bilayers in membranes may be adjusted to maintain fluidity irrespective of growth temperature, has been demonstrated for *Escherichia coli*<sup>1</sup>, *Acholeplasma laidlawii*<sup>2</sup> and *Bacillus stearothermophilus*<sup>3</sup>. Even at high temperatures, a minimum amount of unsaturated fatty acid is required for growth of an *E. coli* auxotroph<sup>4</sup>, and generally, for *A. laidlawii* B, at least half the lipids must be in the fluid or disordered state to allow normal growth<sup>5</sup>. Unlike the fatty acid auxotrophs of *E. coli* and *A. laidlawii* used in previous investigations of membrane fluidity<sup>2,4,5</sup>, a fatty acid auxotrophic *Butyrivibrio* sp. (strain S2) isolated from the ovine rumen was found to be unable to synthesise long-chain fatty acids and incorporated palmitic acid, without desaturation, into lipids of the plasmalogen type partially as a new long-chain dicarboxylic acid<sup>6</sup>. This gave an opportunity to study the lipid composition of a microorganism with a defined fatty acid availability, and also to study the state of fluidity of its membranes in the complete absence of acyl chain unsaturation. We report here a study of membrane lipid fluidity in *Butyrivibrio* S2 using the electron spin resonance (ESR) probe 5-doxylstearic acid. Considerable rigidity of hydrocarbon chains is demonstrated but a phase change or structural reorganisation occurs at the lowest temperature, allowing optimal growth of the organism.

After incorporation of [1-<sup>14</sup>C]palmitic acid into *Butyrivibrio* S2 the long-chain <sup>14</sup>C-labelled hydrophobic moieties produced by methanolysis of the complex bacterial lipids (Table 1) consisted of: (1) about 7% cetyl alcohol; (2) some 40% of the dimethyl

**Fig. 1** *a*, Temperature dependence of maximum hyperfine splitting ( $2T_{11}$ ) for 5-doxyzystearic acid incorporated into whole cells (○) or extracted lipids (●) of *Butyrivibrio* S2 and the relationship between growth temperature and the increase in culture turbidity ( $\Delta A_{450}$ ) in 24 h. *b*, Temperature dependence of maximum hyperfine splitting ( $2T_{11}$ ) for 5-doxyzystearic acid incorporated into multilamellar structures of dipalmitoyllecithin. The gel straight line is a least squares fit to the experimental data. The discontinuities at 33.5 and 41 °C are consistent with the pre- and main transition temperatures reported previously<sup>14</sup>. 5-Doxyzystearic acid was mixed with the extracted bacterial lipids or dipalmitoyllecithin in chloroform/methanol (2:1 v/v) in the molar ratio of ~1:300. The mixed lipid was readily dispersed in D<sub>2</sub>O by a method described previously<sup>15</sup>. In spin-label experiments using whole cells, residual cysteine from the growth medium which could destroy the nitroxide radical<sup>3,16</sup>, was removed by washing the cells four times with 0.1 M phosphate buffer, pH 7.4. The 5-doxyzystearic acid (0.5–1% of the calculated dry weight of lipid in the cells, assuming an average molecular weight of 1,500) was dried down from chloroform/methanol (2:1 v/v) solution in a round-bottom flask and the dry film was incubated with the cell suspension with shaking for 15 min. ESR measurements were carried out with a Varian E 104A (X band) spectrometer equipped with a variable temperature accessory ( $\pm 1^\circ$  heating rate  $20^\circ\text{C h}^{-1}$ ). Samples were contained in 0.1 ml glass or quartz capillaries accommodated within standard 4 mm quartz ESR tubes. Bacterial growth was determined turbidimetrically ( $A_{450}$ ).

ester of a new type of long-chain dicarboxylic acid which had been formed in the bacterium by a dehydrogenation condensation reaction involving two palmitic acid molecules, and has recently been identified as 15,16-dimethyltriacontan-1,30-dioic acid (diabolic acid); (3) 41–42% of long-chain aldehyde (as the dimethylacetal derived from plasmalogen), consisting predominantly of palmitaldehyde but with a little stearaldehyde; and (4) a smaller long-chain fatty acid methyl ester component (9–11%) consisting largely of palmitic acid but with a trace of stearic acid. The complex lipids also contained appreciable quantities of esterified but unlabelled butyric acid.

As with only palmitic acid available for growth, no unsaturation or cyclopropane moieties occur in the hydrophobic chains of *Butyrivibrio* S2, the bacterium possesses no fatty acid desaturase system. Furthermore, as the organism cannot synthesise long-chain fatty acid<sup>6</sup>, it is likely that the low concentrations of stearic acid and stearaldehyde present are derived from trace impurities of stearic acid in the palmitic acid or other medium components. No radioactivity was detected in the stearic acid when the organism was grown in the presence of [ $1-^{14}\text{C}$ ]palmitic acid, indicating that it had not been formed by chain elongation.

The fluidity of the organism's membranes and the lipids extracted from them was examined by ESR using the probe 5-doxyzystearic acid (*N*-oxyl-4',4'-dimethylloxazolidine derivative of 5-ketostearic acid, I(12, 3); Synvar). At all temperatures examined the spectra of the spin label present in either whole cells or the lipid dispersion were typical for highly anisotropic

motion. Table 2 shows a comparison of the published values of the maximum hyperfine splitting  $2T_{11}$  for 5-doxyzystearic acid bound to various cell membranes at temperatures between 15 and 25 °C; it is clear that *Butyrivibrio* S2 grown with a palmitic acid supplement shows a degree of order in its membrane matched only by the rigid, specialised purple membrane of *Halobacterium* spp. At the growth temperature of the organism (39 °C) the maximum hyperfine splitting was  $2T_{11} = 55.5$  G (Fig. 1a), a value similar to that observed with the same label in dipalmitoyllecithin bilayers below the  $T_c$  (in the gel phase) (Fig. 1b), in which the hydrocarbon chains are packed in an orderly crystalline lattice.

The temperature dependence of the maximum hyperfine splitting ( $2T_{11}$ ) of the spectrum of 5-doxyzystearic acid bound to whole cells was compared with that obtained when the same label was incorporated into the lipids extracted from such cells. Plots of  $2T_{11}$  against the reciprocal of absolute temperature (Fig. 1a) showed discontinuities at 34.5 °C for the whole cells and 35.5 °C for the extracted lipids, indicating some type of phase change or structural reorganisation in membrane lipids. This temperature coincided with the lowest temperature at which optimal growth occurred in a palmitate-supplemented medium (Fig. 1a). The single break in the Arrhenius plot (Fig. 1a) probably reflects the relative simplicity of the lipid hydrocarbon chains, which exhibit little variation in chain length, and no unsaturation or cyclopropane substitution as is usually seen in bacterial lipids. Clearly this latter heterogeneity in the fatty acid chains is unnecessary for bacterial growth, a conclusion also recently reached by Silvius and McElhaney<sup>8</sup>, using *A. laidlawii* B grown in the presence of antilipogenic agents.

It is significant that the break in the Arrhenius plot (Fig. 1a) coincides with the minimum temperature that allows optimal growth in a palmitate-supplemented medium. What are the structural changes that occur in the lipid bilayer at that temperature and are apparently necessary for membrane viability and vigorous growth of *Butyrivibrio* S2? The membrane lipids of *Butyrivibrio* S2 possess no unsaturation except the vinyl ether unsaturation in the plasmalogen chains. However, there is little evidence that plasmalogen when substituted for acyl chains can increase the fluidity of lipid bilayers<sup>9,10</sup>.

**Table 1** Long-chain hydrophobic moieties present in *Butyrivibrio* S2 grown with a palmitic acid supplement

Hydrophobic moieties produced	Structure	% Present	
		Expt 1	Expt 2
Alcohol	C16:0	6.77	6.00
Diabolic acid			
dimethyl ester	(C16:0) <sub>2</sub>	41.03	37.99

	C18:0	2.65	2.15
Fatty acid			
methyl ester	C16:0	8.91	11.06
	C18:0	0.48	1.33

*Butyrivibrio* S2, an obligate anaerobe, was cultured in a virtually fatty acid-free liquid medium containing 0.4% (w/v) galactose, as described previously<sup>6</sup> (medium 3). The palmitic acid ( $30\ \mu\text{g ml}^{-1}$ , and in some experiments [ $1-^{14}\text{C}$ ]labelled) required to promote growth was dispersed in this medium with the aid of sodium taurocholate ( $300\ \mu\text{g ml}^{-1}$ ) except where extracted lipids or washed cells were to be used for ESR experiments, when a growth-limiting concentration of fatty acid ( $20\ \mu\text{g ml}^{-1}$ ) was dispersed in the medium by ultrasonication. Cultures were inoculated with 5% (by vol) inoculum, grown to maximum turbidity in the same medium, and were incubated at 39 °C for 16–18 h. Bacterial cells were collected by centrifugation ( $20,000g$ ; 20 min) and lipids were extracted and analysed<sup>6</sup>. The complex lipids were hydrolysed with 5% (w/v) HCl in methanol (90 °C; 2 h) which converted any esterified long-chain carboxylic acids into their methyl esters and long-chain aldehydes (plasmalogens) into dimethylacetals while any alcohols were liberated as such. Quantification of the hydrophobic moieties was carried out by radioactivity measurements after TLC<sup>6</sup> and the chain lengths present were determined by GLC.

There are two possible ways in which some limited degree of hydrocarbon chain motion could occur in the lipid bilayer. First, it has been shown here and previously<sup>11</sup> that many of the complex glycolipids and phospholipids produced by members of the genus *Butyrivibrio* contain at least one esterified butyryl group per molecule. Such short fatty acid chains are likely to increase the fluidity of a lipid bilayer. Second, the long-chain dicarboxylic acid (diabolic acid) occurring as an integral esterified part of the membrane's phospholipid contains two vicinal methyl groups substituted in the centre of the methylene chain<sup>7</sup>. Such methyl groups are again likely to perturb the orderly packing of the hydrocarbon chain in much the same way that anteiso methyl branched fatty acid molecules pack less readily and consequently have a much lower capillary melting point than their straight-chain or isobranched homologues<sup>12,13</sup>. Indeed, the melting point of 41 °C observed<sup>7</sup> for the dimethyl ester of the diabolic acid

isolated from palmitic acid grown *Butyrivibrio* S2 cells is much less than that predicted from the melting points of the homologous series of straight-chain dicarboxylic acid diesters. To a certain extent the role of the diabolic acid could be equivalent to that believed to be played by the high levels of anteiso branched fatty acyl groups found in psychrophilic microorganisms when compared with their closely related mesophilic counterparts<sup>12</sup>. These acids, together with the greater percentage of unsaturated fatty acyl chains, help to maintain membrane fluidity at the lower growth temperature of the psychrophilic organisms. However, this fluidising effect of the vicinal methyl groups in diabolic acid might be partly counterbalanced by the very long hydrocarbon chain which may span the membrane bilayer thus reducing the cooperative lipid motion.

We believe that the present naturally-occurring auxotroph has survived in the rumen through its ability to make use of the abundance of saturated fatty acid (both palmitic and stearic acid) and *trans* octadecenoic acid formed by biohydrogenation occurring in this environment. When grown on palmitic acid, the bacterium incorporates this fatty acid exclusively into the lipid part of its membranes, resulting in a very rigid membrane

structure as indicated by the large hyperfine splitting (Table 2). Although *Butyrivibrio* S2 has no capacity to shorten chains or desaturate the fatty acids available from the environment or convert these into a cyclopropane form, it may nevertheless decrease the rigidity of its lipid bilayers by: (1) introducing butyryl groups produced by the fermentation of hexoses, and (2) introducing anteiso-type branching by a novel type of condensation reaction between two palmitic acid chains. These structural features are probably responsible for some kind of molecular motion in the lipid bilayer, which, though rather restricted, is sufficient to maintain the functions of the membrane at growth temperatures above 34 °C. The ESR measurements indicate that the membranes of the organism have a tightly packed, highly ordered lipid bilayer even at the physiological growth temperature of 39 °C. This suggests that in *Butyrivibrio* S2 a more limited degree of hydrocarbon chain motion is required for membrane viability than has been found in other bacteria.

## Cholesterol modulates activity of calcium-dependent ATPase of the sarcoplasmic reticulum

BIOMEMBRANES consist of an asymmetric lipid bilayer matrix into which and around which the various proteins are situated. The proteins may be attached to the outside of the lipid bilayer (extrinsic proteins), but in many cases the proteins (intrinsic proteins) are embedded within, and can span, the bilayer. Associated with this is the idea that in many cases the lipid matrix is in a fluid condition in which the lipids are essentially above their transition temperature ( $T_c$ ) and able to diffuse along the bilayer length. The perturbation introduced into the lipid bilayer by the presence of an intrinsic protein has recently been discussed<sup>2,3</sup>. Some workers<sup>4,5</sup> have suggested that intrinsic proteins, for example the  $\text{Ca}^{2+}$ -ATPase of the sarcoplasmic reticulum, carry with them, even when excess bulk fluid lipid occurs, a

**Fig. 1** Change in the ratio of cholesterol to phospholipid in SR membranes during incubation in the presence of cholesterol-rich liposomes. SR vesicles ( $1.5 \text{ mg protein ml}^{-1}$ ) were incubated in the absence of liposomes (○), with  $1 \text{ mg dipalmitoyllecithin-cholesterol per ml}$  (○●), or  $2 \text{ mg dipalmitoyllecithin-cholesterol per ml}$  (●) in a medium consisting of  $0.1 \text{ M KCl}$ ,  $5 \text{ mM histidine buffer pH } 7.4$ ,  $100 \text{ U ml}^{-1}$  penicillin-G and  $100 \mu\text{g ml}^{-1}$  streptomycin sulphate. The incubations were performed in siliconised flasks gassed with nitrogen and shaken gently in a water bath maintained at  $20^\circ\text{C}$ .

shell of immobilised lipid, referred to as an annulus, which controls the enzyme activity. The shell is said to exclude cholesterol so that cholesterol molecules do not influence the enzyme activity. We report here the use of cholesterol-enriched liposomes to reversibly vary the content of cholesterol in the sarcoplasmic membranes. We show in contrast to the previous work that as the cholesterol content of the membrane varies so does the activity of the  $\text{Ca}^{2+}$ -ATPase.

Sarcoplasmic reticulum  $\text{Ca}^{2+}$ -ATPase is an example of an intrinsic protein where a single lipid shell of some 30 lipid molecules is bound relatively tightly to the protein. This immobilised layer or annulus is assumed to co-exist with and to be separate from the bulk lipid. The intrinsic protein is then envisaged to exist as a protein-lipid complex undergoing rotational and lateral diffusion within the remaining fluid lipid bilayer<sup>4</sup>. This has led to the suggestion that a similar situation occurs with a major class of other membrane proteins<sup>6</sup>. Methods of changing the cholesterol content of biomembrane systems *in vitro* have now been developed. Incubation of cholesterol-rich liposomes with a variety of cells and subcellular organelles has been shown to cause a rapid exchange of the sterol and there is a

**Fig. 2**  $\text{Ca}^{2+}$ -dependent ATPase activity of SR as a function of the ratio of phospholipid to cholesterol in the membrane. Enzyme assays were performed as described in the text.

net transfer of cholesterol on creation of a concentration gradient<sup>7,8</sup>. We have exploited this system to alter the cholesterol content of sarcoplasmic reticulum (SR) by incubating membrane vesicles with cholesterol-rich liposomes. The effect of introducing cholesterol on the activity of  $\text{Ca}^{2+}$ -dependent ATPase in the natural biomembrane system was examined.

SR isolated from rabbit hind leg muscle has a relatively simple protein and lipid composition<sup>9,10</sup>. More than 60% of the total membrane protein is  $\text{Ca}^{2+}$ -dependent ATPase which is responsible for pumping  $\text{Ca}^{2+}$  from the sarcoplasm into the cisternae of the SR during the recovery phase leading to muscle relaxation. Calcium uptake by SR vesicles has been shown to be stoichiometrically coupled to ATP hydrolysis<sup>11,12</sup>. The membrane-bound enzyme has a molecular weight of about 110,000 and it is partly interpolated into the lipid bilayer<sup>13</sup>.

Preliminary experiments investigated the rate and extent of cholesterol incorporation into SR vesicles. SR, prepared by the method of Martonosi *et al.*<sup>14</sup> and further purified by sucrose density gradient centrifugation<sup>15</sup>, was incubated with cholesterol-rich liposomes. These were prepared by co-lyophilising dipalmitoyllecithin and cholesterol (molar ratio ( $M_1$ ), 1:2) from benzene:methanol 95:5 (v/v) and then sonicating the mixture in a sealed vessel under nitrogen for 12 min at  $30^\circ\text{C}$  in distilled water. After sonication, the liposome suspensions were centrifuged at  $50,000g$  for 60 min to remove undispersed lipid and titanium dislodged from the sonicator probe. Aliquots of the incubation mixture were removed at appropriate time intervals and cholesterol-rich liposomes were separated from SR vesicles by the following procedure. The suspension was diluted with 2 vol.  $0.1 \text{ M KCl}$ ,  $5 \text{ mM histidine buffer pH } 7.4$ , and centrifuged for 30 min at  $50,000g$ . The membrane fraction sedimenting as a pellet was resuspended in 20% (w/v) sucrose buffered to pH 7.4 with  $5 \text{ mM histidine}$  and layered at the interface between 27% sucrose,  $5 \text{ mM histidine}$ , pH 7.4 and  $0.1 \text{ M KCl}$ ,  $5 \text{ mM histidine}$ , pH 7.4. Centrifugation of the gradient for 2 h at  $100,000g$  separates any remaining cholesterol-rich liposomes. These band at the interface of  $0.1 \text{ M KCl}$  and 20% sucrose layers and the SR is recovered as a pellet at the bottom of the gradient.

Figure 1 shows changes in the  $M_1$  of cholesterol:phospholipid in the purified membrane fractions during incubation with cholesterol-rich liposomes. Cholesterol was extracted from the SR by the method of Rose and Oklander<sup>16</sup> after saponification of the lipid, and assayed by quantitative gas chromatography using an internal standard of cholestane. The amount of cholesterol transferred to the membranes can be seen to vary both with the concentration of cholesterol-rich liposomes and with incubation time. No loss of phospholipid<sup>17</sup> or protein<sup>18</sup> from the SR could be detected and there was no incorporation of dipalmitoyllecithin (Table 1) into the membrane as judged from the pattern of fatty acid methyl esters separated by gas chromatography<sup>19</sup>. In separate control experiments, membrane vesicles were incubated with pure dipalmitoyllecithin liposomes which, in contrast to cholesterol-rich liposomes, could not be separated from the SR by the method described. Fusion of the cholesterol-rich liposomes with the membrane is excluded on the basis of freeze-fracture electron microscopy which shows two distinct populations of vesicles, one with prominent intramembrane particles, believed to represent intrinsic protein of the SR, and the other devoid of particles, presumably the phospholipid liposomes. Adhesion of liposomes to the vesicles did not effect  $\text{Ca}^{2+}$ -ATPase throughout the 7-h incubation.

The relationship between  $\text{Ca}^{2+}$ -dependent ATPase activity and the cholesterol content of the SR membrane is shown in Fig. 2. Calcium-dependent ATPase activities were measured at  $32^\circ\text{C}$  in the presence of an ATP regenerating enzyme system. The assay medium consisted of  $0.1 \text{ M triethanolamine buffer pH } 7.4$ ,  $0.1 \text{ M KCl}$ ,  $5 \text{ mM MgCl}_2$ ,  $0.5 \text{ mM EGTA}$ ,  $3 \text{ mM Mg-ATP}$ ,  $1.25 \text{ mM phosphoenolpyruvate}$ ,  $0.2 \text{ mM NADH}$ , pyruvate kinase (20 IU) and lactate dehydrogenase (20 IU) in a total volume of 3 ml. The SR was preincubated in the assay medium for at least 10 min and the  $\text{Ca}^{2+}$ -independent ATPase activity determined:  $\text{Ca}^{2+}$ -dependent ATPase was then measured

**Table 1** Analysis of SR vesicles before and after incubation

following addition of CaCl<sub>2</sub> to give a final assay concentration of 0.55 mM. The rate of oxidation of NADH was monitored on a recording spectrophotometer.

It can be seen that Ca<sup>2+</sup>-stimulated enzyme activity is decreased in direct proportion to the cholesterol content of the membrane over the range examined. Cholesterol is known to restrict the motion of disordered fatty acyl chains of pure phospholipid dispersions or phospholipids in biological membranes<sup>20,21</sup>. This results in a reduction in enthalpy of the lipid thermotropic phase transition and a decrease in fluidity of membranes at temperatures above the phase transition temperature. Recent physical studies of SR membranes using high angle X-ray diffraction, NMR spectroscopy and calorimetric techniques have suggested that the lipids are all in a liquid-crystalline state<sup>22,23</sup> above 10 °C. The effect of cholesterol on Ca<sup>2+</sup>-dependent ATPase is therefore consistent with an effect on the fluidity of the SR membrane.

**Fig. 3** Restoration of Ca<sup>2+</sup>-ATPase activity on removal of added cholesterol. SR (1.5 mg protein per ml) was incubated in the presence of 2 mg dipalmitoyllecithin-cholesterol per ml for 3 h followed by incubation with 1 mg of egg-yolk lecithin per ml for 3 h (●), or in the absence of liposomes (○). *a*, Cholesterol content of the membranes at intervals during incubation; *b*, corresponding Ca<sup>2+</sup>-ATPase activities.

To investigate this further and to discount the possibility that cholesterol interacts directly with the enzyme to cause an irreversible loss of activity, cholesterol was removed from cholesterol-supplemented membranes. Figure 3 shows results for a membrane preparation incubated with cholesterol-rich liposomes and subsequently with liposomes of egg-yolk lecithin to partially re-extract the incorporated cholesterol.

Qualitatively similar results were obtained when SR was incubated with lower liposome concentrations (1 mg ml<sup>-1</sup>). Removal of cholesterol from the SR membranes results in a corresponding recovery of Ca<sup>2+</sup>-dependent ATPase activity. This confirms that cholesterol does not irreversibly inactivate the enzyme and that the presence of cholesterol in the membrane causes a modulation of the Ca<sup>2+</sup>-ATPase activity. The only interpretation possible for these results is that if an annulus as envisaged by Warren *et al.*<sup>5</sup> does exist around this protein then cholesterol is not excluded. This is in contrast to the conclusion of these workers.

The existence of such an annulus has been recently questioned. Studies have shown that almost full enzymatic activity can be recovered after replacing virtually all of the membrane phospholipids with suitable detergents<sup>24</sup>. Furthermore, biochemical<sup>25</sup> and biophysical evidence (for example <sup>2</sup>H NMR and ESR spectroscopy)<sup>26</sup> is considered to be inconsistent with the assumptions inherent in the annulus concept.

This investigation was aided by a grant from the Muscular Dystrophy Association Inc. T.D.M. was supported by a MRC studentship. Support from the Wellcome Trust is also acknowledged.

## ATP induces nucleotide permeability in rat mast cells

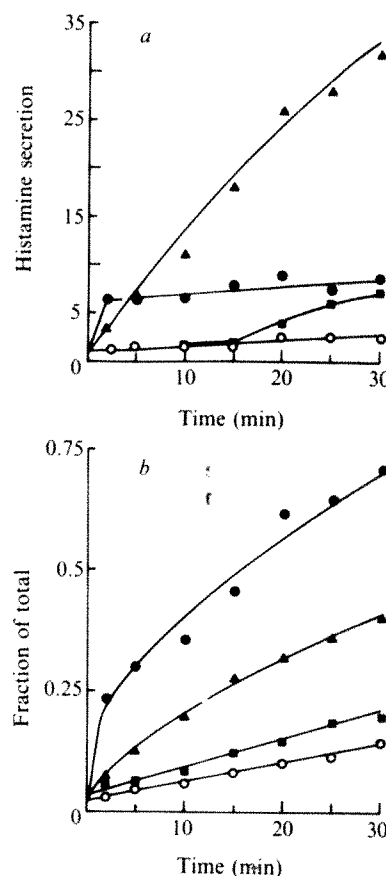

ATP is one of several agonists which stimulate  $\text{Ca}^{2+}$ -dependent exocytotic degranulation of mast cells, causing the release of histamine and other mediators of immediate hypersensitivity<sup>1-3</sup>. The concentration-effect relationship of ATP on mast cells is characterised by the sharp onset of self-inhibition as the concentration is raised above the optimum for histamine secretion<sup>4</sup>. We have previously shown that stimulation of mast cells with IgE-directed ligands (antigen, concanavalin A), chymotrypsin and compound 48/80 is accompanied by an increased turnover of phosphatidylinositol<sup>5</sup> similar to that observed for  $\text{Ca}^{2+}$ -mediated responses in other tissues<sup>6</sup>. At concentrations of ATP which cause inhibition we have observed a reduction in phosphatidylinositol turnover to less than control levels (unpublished results). We show here that the inhibition by ATP is correlated with an extensive leakage of phosphorylated metabolites from the cells.

The effective agonist form of ATP is  $\text{ATP}^{4-}$  (refs 3, 4); that is, the ATP which remains unbound to the divalent cations  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$ , which are normal components of physiological salt solutions. Optimal concentration for  $\text{ATP}^{4-}$ -mediated secretion is about  $3 \mu\text{M}$ . With  $\text{ATP}^{4-}$  applied at  $5 \mu\text{M}$ , inhibition of secretion due to itself<sup>4</sup> or other ligands is almost total<sup>7</sup> and a parallel inhibition of glycolytic metabolism has also been observed<sup>8</sup>. Rat peritoneal mast cells were preincubated with  $^{32}\text{P}$ -phosphate, washed free of external radioactivity and purified to better than 95% homogeneity (see Fig. 1 legend). When we applied ATP to these cells at a concentration optimal for secretion (Fig. 1a) (at which  $\text{ATP}^{4-}$  was calculated to be  $2.9 \mu\text{M}$ ), we found that there was an increased efflux of  $^{32}\text{P}$ -labelled material from the cells (Fig. 1b). As the concentration of free ATP was raised to  $8.6 \mu\text{M}$ , histamine secretion was prevented (Fig. 1a) but the loss of  $^{32}\text{P}$ -labelled material increased (Fig. 1b). ATP applied to the cells at concentrations below the optimum for secretion had only a small effect on the loss of label (Fig. 1a, b).

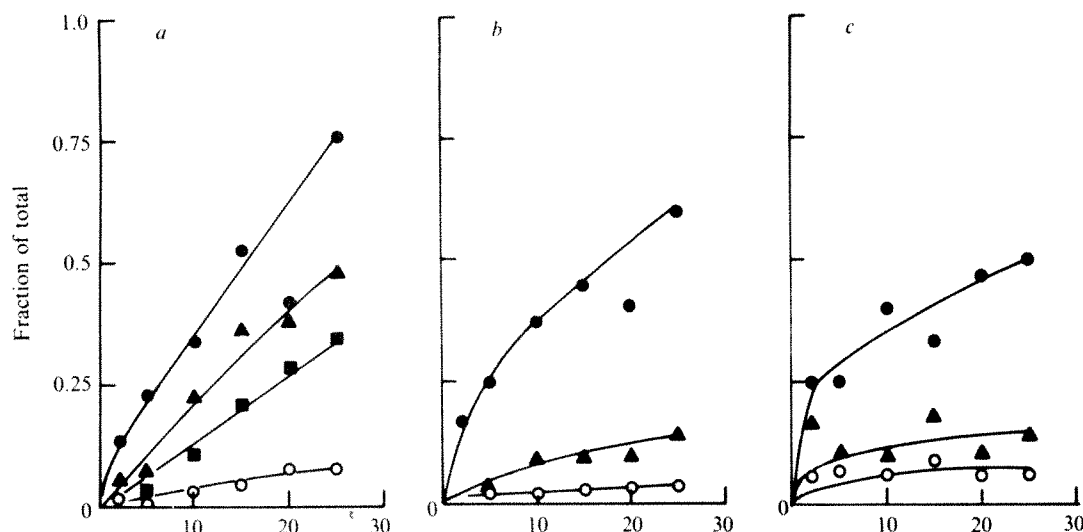

We separated the extracellular material into three fractions by passage through activated carbon (to separate nucleotides)<sup>9</sup> and by extraction into isopropylacetate, after formation of the phosphomolybdate complex to separate inorganic phosphate from organic phosphates (probably phosphorylated intermediates of glycolytic metabolism)<sup>10</sup>. Figure 2 shows the appearance of radioactivity in these three fractions as functions of ATP concentration and time.

At low concentrations ( $1.4 \mu\text{M}$  free ATP, sub-optimal for secretion) the labelled material appearing outside the cells is entirely in the form of inorganic phosphate. As the concentration of free ATP is raised through  $2.9 \mu\text{M}$  (optimal for secretion) to  $8.6 \mu\text{M}$  (inhibitory) the rate of loss of inorganic phosphate from the cells increases, but in these conditions a considerable loss of nucleotides and other  $^{32}\text{P}$ -labelled material also occurs. This loss of metabolites is not a consequence of exocytotic degranulation, as extensive histamine secretion due to application of compound 48/80 is not accompanied by the appearance of labelled metabolites in the extracellular medium.

Loss of metabolites on this scale would be quite sufficient to account for the inhibitory effects of externally applied ATP on glycolysis<sup>8</sup> and the ATP-induced phosphatidylinositol response. Exogenous ATP is known to permit the leakage of intracellular anions (including nucleotides) from some transformed (but not

**Fig. 1** a, Time course of histamine secretion from purified rat peritoneal mast cells, induced by various concentrations of ATP. b, Time course of ATP-induced loss of  $^{32}\text{P}$ -labelled metabolites from mast cells. Rat peritoneal cells were obtained by peritoneal lavage and suspended in 2 ml of a balanced salt solution (composition previously described<sup>5</sup>). The mixed cells were loaded with  $^{32}\text{P}$ - $\text{PO}_4$  ( $100 \mu\text{Ci ml}^{-1}$ , carrier-free) by incubation at  $37^\circ\text{C}$  for 2 h. The mast cells were then isolated from the extracellular  $^{32}\text{P}$ - $\text{PO}_4$  and purified to >95% homogeneity by centrifugation ( $400g$ , 15 min) through a cushion of Ficoll (30%) as described elsewhere<sup>5</sup>. The purified mast cells were then washed twice by centrifugation and suspended in the balanced salt solution at  $5 \times 10^5$  cells per ml. The cells were incubated at  $37^\circ\text{C}$  with concentrations of ATP as indicated. At various times  $250 \mu\text{l}$  were removed and quenched into 1 ml of ice-cold saline. After centrifugation at  $4^\circ\text{C}$  ( $400g$ , 5 min) samples of supernatant were removed for measurement of radioactivity and of histamine (method as previously described<sup>17</sup>). Both the total and free ATP concentrations are indicated; free ATP concentrations were calculated from equilibrium considerations with  $K_{(\text{Mg}, \text{ATP})} = 10^{4.28}$  and  $K_{(\text{Ca}, \text{ATP})} = 10^{3.94}$  (ref. 4). ATP concentration ( $\mu\text{M}$ ) (total/free):  $\circ$ , 0/0;  $\blacksquare$ , 50/1.4;  $\blacktriangle$ , 100/2.9;  $\bullet$ , 300/8.6.

**Fig. 2** Time course of ATP-induced loss of inorganic phosphate (a), non-nucleotide organic phosphates (such as sugar phosphates) (b), and nucleotides (c), from prelabeled mast cells. After incubation for various times in the presence of ATP, the supernatants were collected as described in Fig. 1, and samples fractionated as described in the text. Free ATP concentration ( $\mu\text{M}$ ):  $\bullet$ , 8.6;  $\blacktriangle$ , 2.9;  $\blacksquare$ , 1.4;  $\circ$ , 0.

untransformed) cell lines<sup>11</sup>, but we stress that this effect of ATP occurs at concentrations more than two orders of magnitude above that which causes leakage of metabolites from mast cells. The effect on mast cells shows specificity for ATP; 2-deoxy ATP showed a small effect when applied at 500  $\mu\text{M}$  (total concentration), and CTP, GTP, ADP, adenosine and the synthetic ATP analogue, adenylylimidodiphosphate, were without effect when applied at 1 mM (total); they did not prevent the action of ATP.

The affinity of the ATP receptor on mast cells is of the order of  $10^6 \text{ l mol}^{-1}$  but this might be modulated by the presence of divalent cations. In the absence of divalent cations nucleotide loss from mast cells began with  $\text{ATP}^{4-}$  applied at 1  $\mu\text{M}$  and was maximal with  $\text{ATP}^{4-}$  at 3  $\mu\text{M}$ , conditions which permit only the loss of inorganic phosphate in the presence of  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  (see Fig. 2). The divalent cations which were present in our experiments to act as buffers for the ATP and to permit secretion may thus additionally confer protection on the cells against the detrimental effects of ATP. We cannot say whether the ATP receptor responsible for enhanced anion permeability is the same as that which stimulates phosphatidylinositol turnover,  $\text{Ca}^{2+}$  and  $\text{Na}^{+}$  fluxes<sup>12</sup> and histamine secretion. The enhanced permeability does not extend to macromolecules (leakage of lactate dehydrogenase was less than 5%) and is in no sense lytic.

Perhaps the most interesting observation is the graded response to molecules of increasing molecular weight as the concentration of ATP applied to the cells is increased. Thus, free ATP at 1.4  $\mu\text{M}$  enhances the permeability of the mast cells only to inorganic phosphate, which increases as the concentration of free ATP is raised to 2.9  $\mu\text{M}$ . It is only above this level that sugar phosphates and nucleotides begin to appear. This indicates that as the concentration of external ATP is raised, a change occurs in the filtration properties of the anion channels through which the intracellular metabolites emerge. One possibility is the successive involvement of channels of different specificity; alternatively, it would result from variation in the dimensions of a single channel type. A possible mechanism would involve channel formation by the aggregation of transmembrane monomeric units in the manner which has been discussed with respect to the channels formed by the polyene antibiotics<sup>13</sup> and alamethicin<sup>14</sup>. In the latter case it has been argued that enlargement of pre-formed channels occurs by the recruitment of additional monomers into the oligomeric conducting unit. The conductivity of the junctional membrane channels of *Chironomus* salivary gland varies inversely with the concentration of intracellular  $\text{Ca}^{2+}$  (ref. 15) and this correlates with variation in the size exclusion limits for transfer of a series of fluorescent dyes between neighbouring cells<sup>16</sup>. In this case, too, it has been suggested that the variable filtration characteristics could arise from alterations in effective channel size.

## Choline transport is not coupled to acetylcholine synthesis

It has been proposed<sup>1–3</sup> that choline transport, particularly that performed by the so-called high-affinity system, is obligatorily coupled to acetylcholine synthesis and therefore only choline that has just entered by the transport mechanism is acetylated. If this were so it would imply that the enzyme choline acetyltransferase is bound close to the transport sites on the membrane. The problem is important because of its implications for the molecular organisation of the synapse and also because subcellular fractionation studies<sup>4,5</sup> show fairly clearly that, at the ionic strengths prevailing inside the cell, choline acetyltransferase is soluble and not bound to the plasma or synaptic vesicle membrane (as would be expected if the hypothesis of obligatory coupling is true). The evidence for this is indirect and relies on the finding that the half-maximal concentration for acetylation of choline and its analogues *in situ* approximates more nearly to the half-maximal concentration of their transport than of their acetylation by the isolated enzyme<sup>1</sup>. However, this

**Fig. 1** Utilisation of external choline for ACh synthesis. Synaptosomes were preincubated as described in the text with  $8 \mu\text{M}$   $^{14}\text{C}$ -glucose ( $304 \mu\text{Ci } \mu\text{mol}^{-1}$ ) and then washed and incubated for 10 min with different concentrations ( $\bullet$ ,  $0.2 \mu\text{M}$ ;  $\blacktriangle$ ,  $0.8 \mu\text{M}$ ;  $\blacksquare$ ,  $10 \mu\text{M}$ ) of choline at various specific activities. Dashed line shows theoretical 100% curve. Each point is the result of separate incubation.  $\nabla$ , Incubation carried out in  $24 \text{ mM K}^+$  which depolarises and causes ACh release. Ordinate, specific activity of the  $^3\text{H}$ -ACh synthesised during the 10 min incubation with  $^3\text{H}$ -choline.  $^{14}\text{C}$ -ACh present in synaptosomes just before the addition of the pulse was  $533 \pm 56 \text{ d.p.m. per mg}$  (s.e.m.,  $n = 10$ ) and rose to  $917 \pm 28 \text{ d.p.m. per mg}$  (s.e.m.,  $n = 20$ ) during the 10-min choline pulse.

need only imply a coupling between transport and synthesis if the latter is rate controlling, and from a survey<sup>6</sup> of the rates of release and synthesis of acetylcholine (ACh) it seems that the activity of choline acetyltransferase is in considerable excess of normal requirements. Certain exceptions to the obligatory coupling of transport and synthesis have been noted but these involve synthetic analogues of choline<sup>7</sup> or unusual preparations<sup>8,9</sup>. Reduction of the acetyl-CoA levels reduces ACh concentrations without a concomitant reduction in choline transport<sup>10</sup> but neither this nor the previous studies exclude the possibility that the residual ACh synthesis remains coupled; that is, obligatorily dependent on choline that has just been transported across the membrane. We describe here an experiment which we believe demonstrates that choline that has been recently transported has no privileged access to choline acetyltransferase in the synaptic terminal. Instead it mixes with the pre-existing pool of choline and therefore there is no coupling between transport and synthesis.

The principle of the experiment is that if there was obligatory coupling only choline originally outside the synaptic terminal would be acetylated. If, therefore, the terminals are exposed to pulses of choline of different specific  $^3\text{H}$ -radioactivities, the specific activity of the choline moiety of ACh synthesised inside the terminal during the pulse should be exactly that of the choline to which the terminals were exposed. Quantitatively, a plot of the specific activity of the recently synthesised ACh

against the specific activity of the choline pulse will have a slope numerically equivalent to its contribution towards ACh synthesis. This will be unity if coupling is obligatory, and will decrease as the contribution of the transported choline to the total amount of choline utilised decreases.

To distinguish recently synthesised ACh from pre-existing stores and estimate its specific radioactivity, acetyl CoA was labelled by pre-incubation of synaptosomes with  $^{14}\text{C}$ -glucose. The specific  $^{14}\text{C}$  radioactivity of the ACh synthesised during the  $^3\text{H}$ -choline pulse will be identical to the specific  $^{14}\text{C}$  radioactivity of the acetyl CoA during the period of the pulse. As specific activities are ratios of radioactivity to moles the denominators cancel and the specific  $^3\text{H}$  radioactivity of the recently synthesised ACh is given by the ratio of  $^3\text{H}$ - to  $^{14}\text{C}$ -labelled ACh synthesised during the pulse, multiplied by the specific  $^{14}\text{C}$  radioactivity of the acetyl CoA.

Nerve terminals from cerebral cortex (synaptosomes) were used because although they are heterogeneous with respect to the transmitter, their metabolic characteristics are understood better than alternative preparations of cholinergic synaptosomes. The characteristics of carrier-mediated choline transport in these particles compare favourably with that in intact tissues<sup>11</sup>. The synaptosomes were isolated by conventional procedures, introduced into and washed twice with a physiological saline containing  $180 \text{ mM NaCl}$ ,  $3 \text{ mM KCl}$ ,  $2 \text{ mM CaCl}_2$ ,  $2 \text{ mM MgCl}_2$  and  $8 \text{ mM NaPi}$  ( $\text{pH } 7.2$ ) but without glucose.  $^{14}\text{C}$ -glucose ( $8.2 \mu\text{M}$ ,  $304 \mu\text{Ci } \mu\text{mol}^{-1}$ ) was then added and the synaptosomes incubated at  $37^\circ\text{C}$  for 60 min to label the acetyl CoA. The low concentration of glucose was used to achieve a satisfactory incorporation of radioactivity into acetyl CoA with reasonable economy of isotope. Some experiments were carried out at a glucose concentration of  $0.5 \text{ mM}$  with similar results. These and a comparison of the uptake of  $^3\text{H}$ -choline and conversion to  $^3\text{H}$ -ACh at higher glucose concentrations are given in Table 1.

After the incubation an aliquot of the suspension was taken to determine the initial value of  $^{14}\text{C}$ -ACh. The  $^3\text{H}$ -choline pulse was then added so that the final concentrations of choline were  $0.2$ ,  $0.8$  and  $10 \mu\text{M}$  and at each concentration there were three different specific activities in the range  $50$ – $10,000 \mu\text{Ci } \mu\text{mol}^{-1}$ . After 10 min the synaptosomes were sedimented by a rapid ( $5\text{-s}$ ) centrifugation in a Janetski centrifuge and the washed pellets taken for analysis.  $^3\text{H}$  and  $^{14}\text{C}$  radioactivities in ACh were determined after extraction and thin layer chromatography<sup>12</sup>. The specific radioactivity of the  $^{14}\text{C}$ -acetyl CoA was measured after trichloroacetic acid extraction by removing the choline with two washes of sodium tetraphenylboron ( $10 \text{ mg ml}^{-1}$ ) in vinyl acetonitrile and then allowing the acetyl CoA to acetylate enzymatically radioactive  $^3\text{H}$ -choline of known specific activity using the choline acetylase of a brain acetone powder. The

The influx of  $^3\text{H}$ -choline and synthesis of  $^3\text{H}$ -ACh were measured at the various choline and glucose concentrations in separate experiments<sup>14</sup> and are expressed as pmol per mg synaptosomal protein. The fractional utilisation of external choline was calculated from the slopes of plots made as in Fig. 1. In the last column the influx of choline in 10 min is expressed as fraction of the total synaptosomal content of endogenous choline determined in separate experiments<sup>14</sup> as  $400 \text{ pmol per mg synaptosomal protein}$ .

specific  $^{14}\text{C}$  radioactivity of the synaptosomal acetyl CoA was  $2.2 \mu\text{Ci } \mu\text{mol}^{-1}$  and it did not change significantly during the pulse.

The results for a typical experiment are shown in Fig. 1. As expected the points fall on straight lines passing through the origin. Duplicate data show reasonable agreement. Incubating the synaptosomes in a depolarising medium<sup>13</sup> so that they released ACh had little effect. The slopes are much less than unity at choline concentrations of  $0.2\text{--}0.8 \mu\text{M}$ , but increase to about 0.5 at choline concentrations of  $10 \mu\text{M}$ . This means that for the synthesis of ACh there is a substantial dilution of the external choline by the choline pre-existing in the terminal, and therefore there does not seem to be any coupling of transport to synthesis. Furthermore as the choline concentration was increased out of the 'high-affinity' range the slopes increased, indicating a greater utilisation of external choline. This is the opposite to what would be expected if the high-affinity uptake alone was coupled to ACh synthesis, as at higher choline concentrations its effect would be swamped by the low-affinity uptake. In fact the utilisation of external choline agrees tolerably well with the contribution of influx to the total synaptosomal choline pool, as can be seen from the summary of results in column 6 of Table 1.

Synaptosomes derived from cerebral cortex are not all cholinergic but this will not affect our results as non-cholinergic synaptosomes do not synthesise ACh and will therefore not have contributed to the data. We have considered the possibility that efflux of choline from the synaptosomes was diluting the  $^3\text{H}$ -choline in the medium. Choline efflux was measured and although some dilution occurred the qualitative aspects of the experiment were preserved. The uptake of  $^3\text{H}$ -choline and its conversion to  $^3\text{H}$ -ACh are slightly but not markedly reduced (Table 1, columns 3 and 4) by the low concentrations of glucose used in this study. It could be argued that, even though these are relatively unaffected by low glucose concentrations, there might be interference with other aspects of synaptosomal functioning that indirectly affect the results. However, the overall pattern of the coupling is maintained at a glucose concentration differing by 20-fold (that is from  $8 \mu\text{M}$  to  $0.5 \text{ mM}$ ) so it seems reasonable to suppose that this pattern will be preserved at the 2–10-fold higher concentration of glucose conventionally used.

Although these experiments were not designed to demonstrate the existence or otherwise of high-affinity transport systems specifically associated with cholinergic synaptosomes<sup>15–18</sup> they do not support this notion. If there was such a system it would follow that the proportional utilisation of external choline at low concentrations would exceed the utilisation at high concentrations. The reverse is the case; moreover the contribution of transport (measured over the whole population) to the total synaptosomal choline pool is in reasonable agreement with its contribution to ACh synthesis in cholinergic synaptosomes. High-affinity uptake, if it exists, makes only a minor contribution to the synthesis of the transmitter.

## Effects of catecholamines, ATP and ionophore A23187 on potassium and calcium movements in isolated hepatocytes

IN addition to their well known effects on hepatic gluconeogenesis and glycogenolysis, adrenaline and noradrenaline cause a transient net loss of potassium from the liver of many species<sup>1</sup>. Studies with guinea pig and rabbit liver slices have shown this to be a consequence of a predominantly  $\alpha$ -adrenoceptor-mediated increase in the potassium permeability ( $P_K$ ) of the hepatocyte membrane<sup>2–4</sup>. It has recently become possible to isolate hepatocytes in high yield and with cation levels and metabolic capabilities superior to those of slices, and approaching that of the intact tissue<sup>5</sup>. We have now confirmed that the effects of catecholamines on potassium movement can be shown with such cells, and we have obtained evidence to support the suggestion that the potassium loss which follows  $\alpha$ -adrenoceptor activation in guinea pig liver cells is a consequence of an increase in potassium permeability triggered by a rise in intracellular calcium. The mechanism can be blocked by quinine, as in human erythrocytes<sup>19</sup> and barnacle photoreceptors<sup>20</sup>.

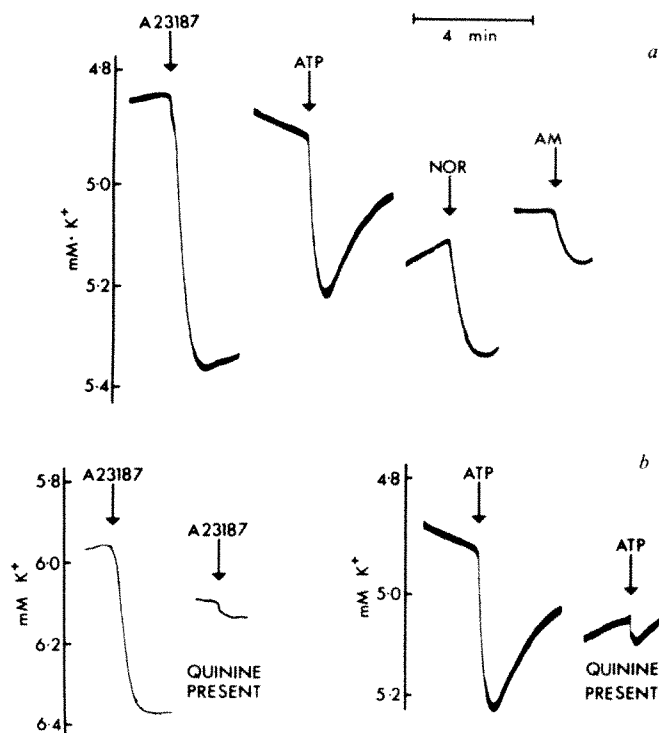

Haylett<sup>4</sup> first raised the possibility that the increase in  $P_K$  in liver cells is a consequence of a rise in the concentration of calcium ions in the cytosol (see also refs 6, 7). Evidence for the two processes envisaged in this proposal, an effect of  $\alpha$ -receptors on intracellular calcium, and control of  $P_K$  by cytosolic calcium, has been obtained in various tissues including salivary and lacrimal glands<sup>6–12</sup>. On such a scheme we could expect the divalent cation ionophore A23187 to initiate potassium loss by increasing cytosolic calcium, and hence  $P_K$ . This was tested with hepatocytes isolated by Seglen's method<sup>13,14</sup> from the liver of male Hartley guinea-pigs (220–300 g). The cells were equilibrated at  $37^\circ\text{C}$  for 30–60 min in Eagle's medium<sup>15</sup> (Wellcome) containing (mM): NaCl, 116; KCl, 5.4;  $\text{CaCl}_2$ , 1.8;  $\text{MgSO}_4$ , 0.81;  $\text{NaH}_2\text{PO}_4$ , 0.96;  $\text{NaHCO}_3$ , 25, and (mg  $\text{l}^{-1}$ ): amino acids, 805; vitamins, 8.1; glucose, 1,000; L-glutamine, 292; phenol red, 10. This was supplemented with 2% albumin (fraction V, Sigma). The pH was maintained at 7.4 by circulating 5%  $\text{CO}_2$  in  $\text{O}_2$  above the cell suspension which was shaken at 120 strokes per min. In some experiments (including those with  $^{45}\text{Ca}$ ), samples of the suspension were filtered to eliminate the largest clumps of cells and then centrifuged at 50g for 2 min. The cell pellet was resuspended either in normal Eagle's medium or in a low-Ca, low-Mg variant (Ca, 0.1 mM; Mg, 0.05 mM) sometimes containing  $^{45}\text{Ca}$  ( $0.2 \mu\text{Ci ml}^{-1}$ ) but without albumin. The viability of the cells was checked before and after each experiment by their ability to exclude Trypan blue (4%). By this test between 80 and 85% of the cells were viable at the time when drugs were applied.

Figure 1 shows that A23187 caused a rapid loss of potassium from the isolated cells, as did the  $\alpha$ -agonists amidephrine<sup>16,17</sup>, phenylephrine (not illustrated) and noradrenaline. ATP was also found to be effective. This is in keeping with the earlier observation<sup>18</sup> that ATP hyperpolarises cells in guinea pig liver slices, presumably by increasing  $P_K$ . The potassium loss was not associated with a change in cell viability. It was greatest with A23187, reaching a maximum of  $23 \pm 2\%$  (s.e.,  $n = 8$ ) of the

initial cell content (about 290 mmol per kg dry weight) within 1 min when the ionophore was applied at 40–80  $\mu\text{mol}$  per litre of cells, corresponding to an added concentration of 1  $\mu\text{M}$ . With maximal doses of ATP and noradrenaline (100 and 5  $\mu\text{M}$  respectively) the loss was 10% with each agent, again within about a minute. This is of the same order (8%) as seen on exposing guinea pig liver slices to 1  $\mu\text{M}$  noradrenaline<sup>2</sup>. The response to the selective  $\alpha$ -agonist amidephrine was somewhat variable, ranging from 7% to as little as 1% in a few preparations.

The next experiments were prompted by the finding of Armando-Hardy *et al.*<sup>19</sup> that in erythrocytes the influence of cytosolic calcium on  $P_K$  is inhibited by quinine. A similar effect has been observed in barnacle photoreceptors<sup>20</sup>. We might then expect this agent to reduce the effectiveness of the ionophore and of the other agents in inducing K loss from liver cells. Figure 1a shows that this is so; the responses to noradrenaline and amidephrine were also inhibited to a comparable extent. The possibility that quinine was acting by interfering with the primary actions of the ionophore (and, by implication, of the other agents causing potassium loss) was tested by examining the effect of quinine on the  $^{45}\text{Ca}$  movements brought about by A23187. The technique used was based on that described for erythrocytes by Ferreira and Lew<sup>21</sup>, and is described in Fig. 2. This illustrates the effect of A23187 on the  $^{45}\text{Ca}$  content of cells equilibrated with the tracer for 30–40 min, long enough to allow most of the cytosolic calcium to exchange<sup>22</sup>. When the external

**Fig. 1** *a*, Application of A23187 (5  $\mu\text{M}$ , about 5  $\times$  the dose for maximum effect), ATP (100  $\mu\text{M}$ ), noradrenaline (NOR; 5  $\mu\text{M}$  in the presence of propranolol at 5  $\mu\text{M}$ ), and of the selective  $\alpha$ -agonist (–) amidephrine (AM 10  $\mu\text{M}$ ) causes isolated guinea pig hepatocytes to lose potassium. The movement of K between the cells and the incubation medium (Ca, 1.8 mM; Mg, 0.81 mM) was followed by means of a K-sensitive electrode<sup>29</sup> in the cell suspension (which contained ~50 mg cells in 2 ml, and was stirred). A downward deflection indicates an increase in K concentration, corresponding to K loss from the cells: in this experiment, the loss in response to A23187 amounted to 19% of the total cell content. *b*, Quinine (1 mM, applied in 20  $\mu\text{l}$  ethanol, 5 min previously) greatly reduces the K loss initiated by A23187 and by ATP: control responses are from the same batch of cells.

**Fig. 2** Effect of A23187 on the  $^{45}\text{Ca}$  content (nmol per mg dry weight) of guinea pig hepatocytes at two calcium concentrations (*a*, 100  $\mu\text{M}$ , *b* and *c*, 1.8 mM).  $^{45}\text{Ca}$  was included in the suspension fluid from zero time onwards. At the times indicated by the points, 100  $\mu\text{l}$  samples of the cell suspension were placed in 1.5 ml Eppendorf tubes containing 300  $\mu\text{l}$  of *n*-butylphthalate and 200–800  $\mu\text{l}$  of 'washing medium'. This contained NaCl (160 mM), EGTA-NaOH (2 mM, at pH 7.4, to remove extracellularly bound  $^{45}\text{Ca}$ ) and  $^3\text{H}$ -inulin, and was maintained at 0–1  $^{\circ}\text{C}$ . Each sample was immediately centrifuged at 12,000g (Eppendorf centrifuge, Model 5412). The supernatant and the oil were sucked off, and the pellet of cells homogenised in 100  $\mu\text{l}$  distilled water.  $^{45}\text{Ca}$  and  $^3\text{H}$ -inulin were measured by liquid scintillation counting. The amount of labelled inulin gave an estimate of the extracellular fluid trapped in the pellet, and this was used to calculate the  $^{45}\text{Ca}$  content of the cells. A23187 was added (at I) in 20–70  $\mu\text{l}$  absolute alcohol to 15 ml of the cell suspensions. (Final A23187 concentrations: *a*, 10  $\mu\text{M}$ , 690  $\mu\text{mol}$  per litre of cells; *b* and *c*, 2.7  $\mu\text{M}$ , 82  $\mu\text{mol}$  per litre of cells.) *b* and *c* are from the same experiment: in *c*, quinine was added in 15  $\mu\text{l}$  ethanol to a final concentration of 1 mM. Note that quinine does not alter the first two phases of the  $^{45}\text{Ca}$  movement caused by the ionophore.

calcium concentration was 1.8 mM (Fig. 2*b*), the ionophore first caused the  $^{45}\text{Ca}$  content of the cells to increase. This occurred during the initial 15–60 s and was probably a consequence of a net calcium influx generated by the ionophore. A period of calcium extrusion then followed, during which the  $^{45}\text{Ca}$  content fell to below the pre-ionophore level. This second phase has already been reported for rat liver cells<sup>23,24</sup>, as well as for several other tissues<sup>25–28</sup>, and has been attributed to the extrusion from the cells of  $^{45}\text{Ca}$  released from intracellular stores which in spermatozoa have been localised to the mitochondria<sup>26</sup>. In keeping with the idea that internal stores are concerned in liver cells, this phase (and the effect on potassium loss) was unaffected when the external calcium was reduced to 100  $\mu\text{M}$  (Fig. 2*a*). However, the initial increase in  $^{45}\text{Ca}$  could then no longer be distinguished, even when the concentration of ionophore was drastically increased (see Fig. 2*a*). This was presumably because the initial influx of calcium initiated by the ionophore was much

smaller. In high external calcium a third phase of  $^{45}\text{Ca}$  re-accumulation was evident 10–30 min after the ionophore was applied. It was quite variable in both rate and magnitude and will not be discussed here since it occurs at a time when the potassium movements were largely complete.

Figure 2c shows that quinine at the same concentration as had greatly reduced the effects on potassium loss did not interfere with the first two phases of the action of A23187 on calcium exchange. Thus inhibition by quinine of the potassium movement must occur at a later stage, and would seem to be due either to uncoupling of the mechanism by which  $P_K$  is influenced by intracellular calcium, or to blockade of the potassium channels.

A surprising additional observation was that the rapid phase of potassium loss so evident on treating guinea pig hepatocytes with A23187, ATP and  $\alpha$ -agonists was lacking in rat liver cells prepared in exactly the same way. With the rat cells A23187 caused a slow loss of potassium which became appreciable only after several minutes, that is, at a time when the rapid release from guinea pig cells was almost complete. This was not because of a reduced effectiveness of the ionophore since the effect of A23187 on calcium exchange was as great in rat as in guinea pig cells. These findings suggest that the calcium-sensitive potassium channel present in guinea pig liver cells (and, by implication, in those of the toad, rabbit, cat and dog, all of which show hyperkalaemia with adrenaline) is either lacking in rat hepatocytes, or exceptionally insensitive to calcium. That a species difference exists in this regard has been suspected<sup>1,6</sup>, although it is surprising that it should be so striking.

## Enhancement of Ca spikes in nerve cells of adult mammals during neurite growth in tissue culture

GENERATION of Na and Ca spikes in various types of vertebrate nerve cells<sup>1–6</sup> indicates that both Na and Ca channels are generally involved in inducing action potentials in their cell bodies. Although it has been suggested that these ionic channels may change their configuration in the plasma membrane, in particular during degeneration of nerve cells<sup>7,8</sup> or during growth of axons associated with ontogenetic differentiation<sup>9–11</sup>, no systematic or quantitative study has been reported. We have recently established a technique to obtain primary culture of nerve cells of mature mammals<sup>12,13</sup>, and have also developed a technique to compare membrane capability of carrying inward Na and Ca currents among nerve cells of various ages in the cell culture. We report here that the capability of membranes to carry Ca currents, as represented by the maximum rate of rise (MRR) of a Ca spike, is enhanced during a particular period of the cell culture, whereas there is no significant change in Na currents. This may be explained as an increase in number of the Ca channels or as a change in conformation of the Ca channels, associated, in part, with neurite outgrowth. As we used nerve cells which had fully differentiated in the host bodies, the possibility of an effect due to ontogenetic differentiation in the tissue culture condition<sup>14–19</sup> can be excluded. The present finding also demonstrates another aspect of nerve cell membrane that ionic channel molecules, especially the Ca channels, can alter their features rather flexibly in the plasma membrane.

Dorsal root ganglia (Th<sub>12</sub> to L<sub>5</sub>) were dissected from adult guinea pigs (200–300 g body weight) in a sterile condition, and their nerve cells were dissociated by vibrating the ganglia in collagenase-containing Gey's medium. The nerve cells were collected by weak centrifugation, 1,500 r.p.m. for 5 min. The nerve cells thus obtained (Fig. 1a) were incubated at 37 °C in collagen-coated 3-cm diameter plastic dishes (Nunc, approximately one ganglion per dish) with the tissue culture medium and with sterile air containing 5% CO<sub>2</sub>. The tissue culture medium contained 75% Eagle's minimum essential medium (Microbiological Associates), 15% horse serum (Microbiological Associates) inactivated by heat (60 °C for 1 h), 9% chick embryo extract and 1% penicillin–streptomycin solution (Flow). The medium was changed two or three times a week. So as to obtain steady and compatible cell culture, we carefully kept the cell culture condition uniform, in particular by using the same lot number of dishes, collagen, drugs and some medium components<sup>12,13</sup>.

During the incubation, the nerve cells became attached to the bottom of the dishes in a few hours and then began to extend their neurites gradually in several directions (Fig. 1b). Active growth of the neurites was seen (Fig. 1c) during the first week of cell culture. After about 1 week in the cell culture, fibroblasts began to grow rapidly in number, and occupied most of the available areas of the bottom of the dishes in a few weeks; thus it often became difficult to see the neurites under the phase contrast microscope. The nerve cells, however, survived in the cell culture for more than 2 months<sup>12,13</sup>.

The nerve cell soma was penetrated carefully by a glass microelectrode (20–30 mΩ, filled with 3 M KCl solution) under direct view by inverted phase contrast microscope. Action potentials were elicited in the nerve cells by intracellular passage of current through the recording microelectrode; the membrane potential was determined using a Wheatstone bridge balance. The MRR of the action potential, which was presumed to be proportional to a transient inward membrane current<sup>20</sup>, was measured using an electronic differentiator. The electrophysiological study was done at room temperature, 26–28 °C; pH of

**Fig. 1** Growth of dorsal root ganglion cells of adult guinea pigs in cell culture. *a*, A nerve cell immediately after being dissociated from a ganglion by collagenase treatment. *b*, A nerve cell after 2 days in cell culture. Neurite outgrowth is seen in several directions. *c*, Nerve cells (arrows) after 5 d in cell culture. The length of neurites was often more than 1 mm at this period of the nerve cell culture. Scale bar, 50  $\mu\text{m}$ .

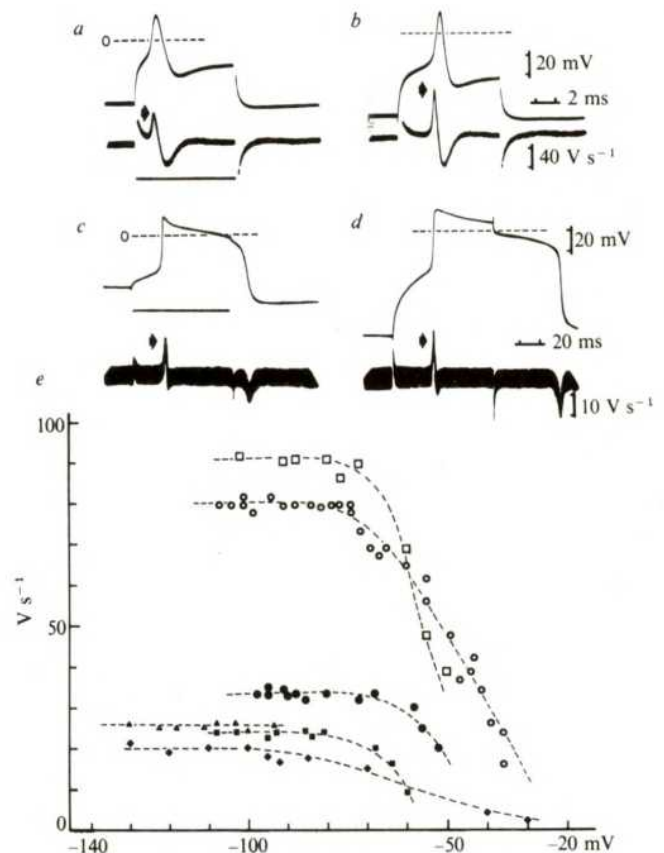

the medium was around 7.4 and was monitored continuously by phenol red.

Figure 2*a* and *b* illustrate spikes elicited in a nerve cell at the resting membrane potential (*a*) and at a hyperpolarised membrane potential (*b*). Judging from their MRRs (arrows in the lower traces), which were proportional to inward membrane currents associated with the respective spikes<sup>20</sup>, the capability of inducing an inward transmembrane current was reduced in the resting membrane (for example, ref. 17) due to a rather small intracellular potential (usually between  $-45\text{ mV}$  and  $-65\text{ mV}$ ). This inactivation was, however, removed by steady hyperpolarisation of the membrane potential below  $-80\text{ mV}$  (Fig. 2*b*: by d.c. current injection), where the MRR became steady at a maximal value which was independent of the membrane potential (Fig. 2*e*, open symbols). We considered this steady maximal value of the MRR as an indicator of the membrane capability of carrying inward current.

This inward current was carried by  $\text{Na}^+$  as the spike generation was blocked either by externally added tetrodotoxin (TTX,  $1.5\text{ }\mu\text{M}$ ) or by total replacement of external  $\text{Na}^+$  with  $\text{Tris}^+$  (data not shown). Although Ca current was possibly elicited in superimposing the spike potential, its contribution to the MRR above seemed to be very small, because the MRR was obtained within 1 ms after the spike onset (Fig. 2*a*, *b*); this delay was too short to elicit a large Ca current in various excitable membranes<sup>21-23</sup>. Furthermore, the external growth medium contained a small amount of  $\text{Ca}^{2+}$  ( $\sim 1.9\text{ mM}$ ) and no blocker of membrane K conductance (see below), which was not sufficient to induce a large inward Ca current in the nerve cell membrane.

A Ca spike (Fig. 2*c*) was elicited in a nerve cell bathed in a Na-free, tetraethylammonium (TEA)-containing medium;  $\text{TEA}^+$  was added to minimise outward K current<sup>24,25</sup>, so that a small inward current could induce regenerative development of the membrane depolarisation. In addition,  $10\text{ mM Ca}^{2+}$  was

added externally to stabilise intracellular recording and to elicit a large spike potential. We used the Na-free medium described above instead of TTX-containing Na-rich medium because a part of the Na current elicited in tissue-cultured nerve cells is resistant to TTX<sup>10-13</sup>. We considered spikes elicited in the Na-free medium to be due to an inward Ca current for the following reasons<sup>26</sup>: (1) their MRRs were related to external Ca concentration ( $2.5\text{--}10\text{ mM}$ ); (2) they were not blocked by TTX high concentrations ( $3\text{ }\mu\text{M}$ )<sup>12,13</sup>; (3) similar spikes were elicited in Na-free, Ba- or Sr-containing medium<sup>12,13</sup> ( $10\text{ mM}$ , instead of  $\text{Ca}^{2+}$ ); and (4), addition of  $\text{Mg}^{2+}$  ( $40\text{ mM}$ ) or  $\text{Co}^{2+}$  ( $4\text{ mM}$ ) suppressed the spike generation. Although a part of the Ca channel activity was blocked at a small resting membrane

**Fig. 2** Na and Ca spikes, and dependence of their MRRs on intracellular potential. *a* and *b*, Na spikes from a nerve cell after 3 days in cell culture at  $-62\text{ mV}$  (*a*) and  $-89\text{ mV}$  (*b*); the holding membrane potential was changed by d.c. current injection through the recording microelectrode. Bar below the record shows a period when a depolarising pulse current is injected intracellularly. Arrow in the lower trace shows the MRR of the spike. Extracellular solution was the tissue culture medium, which contained about  $141.7\text{ mM Na}^+$ ;  $5.0\text{ mM K}^+$ ;  $1.9\text{ mM Ca}^{2+}$ ;  $0.5\text{ mM Mg}^{2+}$ ;  $119.5\text{ mM Cl}^-$ ;  $25.9\text{ mM HCO}_3^-$ ;  $0.9\text{ mM H}_2\text{PO}_4^-$ ;  $0.5\text{ mM SO}_4^{2-}$ ;  $5.5\text{ mM glucose}$ ;  $1.6\%$  protein, and a small amount of amino acids, vitamins, antibiotics and phenol red; pH of the solution was  $\sim 7.4\text{--}7.6$  during the experiment, and was monitored continuously by colour of phenol red. *c* and *d*, Ca spikes at  $-51\text{ mV}$  (*c*) and  $-100\text{ mV}$  (*d*), elicited in a 5-d nerve cell. Repetition rate of the membrane stimulation was kept at less than 2 to 4 per min. External Na-free medium contained  $133.0\text{ mM Tris-HCl}$ ;  $10.0\text{ mM NaCl}_2$ ;  $10.0\text{ mM TEA-Cl}$ ;  $5.5\text{ mM KCl}$ ;  $5.5\text{ mM glucose}$  and a small amount of phenol red at pH 7.4 (for all Ca spikes in this figure). *e*, Dependence of MRRs of Na and Ca spikes on the holding membrane potential. Different symbols indicate spikes from different cells. Open symbols ( $\circ$  and  $\square$ ) are Na spikes from two nerve cells and filled symbols ( $\bullet$ ,  $\blacktriangle$ ,  $\blacksquare$ ,  $\blacklozenge$ ) are Ca spikes from four nerve cells, respectively. When the membrane potential was held below  $-80\text{ mV}$ , the MRRs of both the Na and Ca spikes were maximal and steady values regardless of the membrane potential.

**Fig. 3** Changes in the membrane capability of initiating inward Na and Ca current during cell culture. *a*, MRRs of Na spikes and *b*, MRRs of Ca spikes in volts per second. Na spikes were elicited in the cell culture medium (see Fig. 2 legend and text). Ca spikes were elicited in Na-free medium containing 63 mM Tris-HCl; 80 mM TEA-Cl; 10 mM  $\text{CaCl}_2$ ; 5.5 mM KCl and 5.5 mM glucose at pH 7.4. Filled circles indicate mean values of the MRRs from nerve cells in dishes of the same lot, and bars are their standard deviations. Numbers of nerve cells sampled are indicated below each point.

potential (Fig. 2c), hyperpolarisation of the membrane potential by d.c. current injection removed this inactivation (Fig. 2d) and the MRR of the Ca spike reached a steady value (Fig. 2e: filled symbols). This value may be considered to represent a capability of carrying the inward Ca current of the neuronal membrane.

The MRRs of the Na and Ca spikes thus obtained were compared for cell cultures of nerve cells of various ages (Fig. 3). The MRRs of the Na spikes did not change appreciably during the 4-week period of cell culture in this study (Fig. 3a). By contrast, the MRRs of the Ca spikes exhibited a temporary increase after about 5 to 6 days in cell culture (Fig. 3b), and thereafter, decayed relatively slowly to a steady level which was close to that obtained at the beginning of the nerve cell culture. This temporary increase by a factor of 1.6, relative to the initial or the later level, is statistically significant ( $P < 0.05$ ). It may be significant that when the MRRs of the Ca spikes are large, the nerve cells seem to be actively extending their neurites (Fig. 1c), suggesting that the increment in the MRRs may be related to neurite outgrowth.

Assuming that capacitance of unit area of the membrane<sup>20</sup> remained unchanged, the temporary increase in the MRRs of the Ca spikes can be interpreted as (1) an increase in the number of the Ca channels in the unit area of the soma membrane; or (2) a conformation change in the Ca channel molecules, which allows entry of a larger amount of  $\text{Ca}^{2+}$ . There are, however, other possibilities such as (3), an increase in the sensitivity of the K current to TEA<sup>+</sup>; a part of the K current which remained in the TEA-containing medium might become smaller during the particular period of the cell culture. All these possibilities reflect a definite change at least in the plasma membrane. A further possibility, (4), is an increment in the electromotive force (e.m.f.) of the Ca current; this seems improbable, because, assuming an intracellular Ca concentration ( $[\text{Ca}^{2+}]_i$ ) ranging between  $10^{-6}$  and  $10^{-8}$  M in the early period of the cell culture<sup>27,28</sup>, a 1.5-fold increment of the e.m.f. can be induced only by a new  $[\text{Ca}^{2+}]_i$  of between  $10^{-8}$  and  $10^{-11}$  M, that is, 1/100 to 1/1,000 of the initial  $[\text{Ca}^{2+}]_i$ .

The physiological functions of Ca spikes recorded from the soma of nerve cells are not as clearly understood as those at presynaptic terminals<sup>29</sup>. Hammerschlag *et al.*<sup>30,31</sup> consider that

amino acid uptake and axonal transportation of proteins are intimately related to Ca entry through the soma membrane. It has also been suggested that Ca entry associated with the firing of nerve cells may be an important part of Ca utilised for axonal transportation<sup>32</sup>. In the present study, active neurite outgrowth was seen at least for several days of an early period of the cell culture (Fig. 1b, c), and simultaneously, enhancement of the MRRs of the Ca spikes was observed (Fig. 3b). During this period of the cell culture, the nerve cells must take up large amounts of nutrients and carry out extensive protein transportation in order to produce new neurites. Ca requirement associated with membrane synthesis and neurite outgrowth may be related to the possible enrichment of the Ca channels in the neuronal membrane.

The reduction of the MRRs of the Ca spikes which was observed in the later period of the cell culture (Fig. 3b) suggests that Ca requirement of the nerve cells may have been reduced for some reason (for example, reduction of neurite growth) or that a membrane part where the Ca channels were populated moved to a position remote from the soma. In the later period, however, observation of the neurites of a nerve cell became difficult because of the rapid proliferation of fibroblasts and the complex interactions of neurites originated from many nerve cells. Further study is thus required to investigate the relationship between the neurite growth and change in the Ca spikes recorded from the soma, especially that in the later period of the nerve cell culture.

Note, however, that there are many other possibilities which could explain the background of the change in the Ca spikes. Whatever the interpretation, it is interesting that ionic channels can alter their distribution or conformation relatively flexibly in the plasma membrane of the mature nerve cells.

## Neural influence on acetylcholine receptor clusters in embryonic development of skeletal muscles

THE extent to which innervation regulates the embryonic development of skeletal muscle, and the mechanisms of nerve-muscle trophic interactions during development, are little understood. Here we describe studies on the development of skeletal muscles in rat embryos in which all the motoneurons were destroyed, and experiments in which chronic application of tetrodotoxin (TTX) to individual embryos blocked all nerve and muscle electrical activity during neuromuscular junction formation. The results are presented with special emphasis on the regulation of acetylcholine (ACh) receptor distribution. It is already known that ACh receptors in adult tissues are densely clustered under nerve terminals on both muscle<sup>1</sup> and nerve cells<sup>2</sup>. Relatively few receptors are found in extrajunctional regions, and if these are present at all they are uniformly dispersed. Studies of individually teased muscle fibres from rat embryos have shown receptor aggregates (clusters or hotspots) to be present after 16 d gestation<sup>3</sup>, but no more is known about how these clusters are induced to form or to achieve their proper location. Studies of mouse, chick and toad muscles in tissue culture have shown that receptor clusters may form on myotubes that have developed in the absence of nerve tissue<sup>4-6</sup>. In cultured toad muscle these clusters migrate within the muscle membrane to locate beneath nerve terminals<sup>5</sup>. Here, we show that receptor clusters appear on embryonic rat muscle after 15½ d gestation, with striking synchrony in timing, and an ordering of the position of clusters on different fibres within a muscle. These initial events were little changed after irreversible destruction of motoneurons at 14 d gestation except that additional receptor clusters appeared at later times. Paralysis of developing nerve and muscle with TTX did not affect the appearance and progressive increase in size of junctional clusters, but extrajunctional clusters also appeared, as in the denervated muscles. These experiments show that the first appearance of ACh receptor clusters on embryonic skeletal muscle does not depend

on innervation, but that the final ordering of their position on muscle fibres and their later increase in size do require the presence, although not the electrical activity, of the nerve. Electrical activity of nerve and/or muscle is essential to suppress the appearance of extrajunctional receptor clusters, and for the normal progress of muscle growth. This study shows also that mammalian embryos are more accessible to experimental manipulation than may previously have been realised, so that toxins and metabolites may be chronically applied to embryonic tissues *in vivo*, as well as in tissue culture.

Motoneurons were destroyed by injection of 1 µg of  $\beta$ -bungarotoxin<sup>7</sup> into individual embryos of 14 d gestation or older. Paralysis was not seen in embryos injected at 13 d or earlier. This toxin has been shown to destroy motor nerve terminals<sup>8</sup>, and to cause total loss of motoneurons following injection into chick embryos<sup>9</sup>. We found that a single injection of 1 µg of toxin into individual rat embryos caused a sustained loss of muscle innervation. No recovery of innervation was seen in embryos injected at 14 d and examined at 22 d of gestation. Our evidence for loss of motoneurons in rat embryos includes the absence of nerve fibres in sections of ventral roots examined under the electron microscope, and the absence of large ventral horn neurones in spinal cords of treated embryos. Toxin-treated embryos developed in a grossly normal fashion, although they were lighter in weight than their siblings, and abnormally flexed in posture.

Embryos were paralysed by inserting glass capillaries filled with 1 to 2 µl of 0.03 M TTX into their thoracic or abdominal cavities. One end of each capillary had a pore of 20 µm diameter by 100 µm length to allow slow release of the drug by diffusion. In all cases in which capillaries were fully internalised, embryos remained completely paralysed for at least 3 days, and in control experiments newborn rats were paralysed within 5 min of intra-abdominal insertion of a capillary. Survival rates of 100% were common in groups of embryos treated from 16 d gestation onwards, but implantation of capillaries into 15 d embryos was more difficult.

Clusters of ACh receptors were first seen in normal muscles at 15½ d gestation; before that receptors were diffusely distributed along the developing myotubes (Fig. 1). When first seen, junctional clusters had a mean longest dimension of  $7.84 \pm 0.65$  µm ( $\pm$ s.e.m.). If clusters were present they were seen on the great majority of myotubes within a muscle, indicating that their time of appearance was coordinated throughout the tissue. They were not randomly positioned, but appeared as a band across the midpoint of the developing muscle.

ACh receptor clusters formed on muscle fibres made aneural by injection of  $\beta$ -bungarotoxin at 14 d gestation. Clusters were first seen at 16 d gestation, when they formed a broad band across the middle of the muscle. By 17 d gestation their distribution appeared more widespread than in controls although they did not extend all the way to the tendon ends of muscle fibres. In muscles treated at 14 d and examined at 20 d clusters were randomly positioned along the full length of the muscle (Fig. 2a), with no special accumulation in the middle of the muscle. This is in contrast to normal innervated muscle fibres which have a single cluster near the midpoint of the cell<sup>1,3,10</sup>. Once present, these extrajunctional clusters retained a constant size, with mean maximum dimensions of  $8.97 \pm 0.25$  µm at 16 d, and  $8.96 \pm 0.22$  µm at 20 d gestation. If nerve terminals were destroyed at 17 d and muscles examined after 20 d gestation the endplate clusters remained, and extrajunctional clusters appeared only near the ends of the myotubes, presumably on parts of the muscle that had developed after injection of the toxin. The two types of cluster could be distinguished by their size ( $9.98 \pm 0.26$  and  $6.63 \pm 0.13$  µm) for junctional and extrajunctional clusters, respectively, as well as by their location. Control junctional clusters in untreated littermates at 20 d were  $13.28 \pm 0.29$  µm in length, showing that junctional clusters in the treated muscles ceased their growth on application of toxin.

Paralysis with TTX from 16–19 d or 17–20 d gestation resulted in muscles almost indistinguishable from those treated

**Fig. 1** Autoradiographic demonstration of ACh receptor distribution on early myotubes. *a*, Rat embryo diaphragm muscle after 15 d gestation. Top, phase contrast view of unstained section, showing narrow band of myotubes in the muscle centre, surrounded by myoblasts. Bottom, bright field view to show receptors diffusely scattered over myotubes, but not over myoblasts. No receptor clusters can be resolved at this time. *b*, Muscle after 15½ d gestation, illustrating formation of receptor clusters. Scale bars, 100 µm. Embryos were dated by taking 9 am on the morning when a copulation plug was seen as time zero. Embryos were examined between 9 and 11 am (d), or between 7 and 11 pm (½). Receptor localisation was mapped by incubating muscles with <sup>125</sup>I- $\alpha$ -Naja toxin, washing overnight, fixing in glutaraldehyde-paraformaldehyde, making 20-µm frozen sections, and exposing autoradiographs at 4 °C for 3 days.

**Fig. 2** Autoradiographic demonstration of ACh receptor distribution on embryonic rat diaphragm muscles after denervation or paralysis with TTX. *a*, Aneural muscle from embryo after 20-d gestation injected with  $\beta$ -bungarotoxin at 14 d. Receptor clusters are scattered randomly from end to end of the muscle, and no endplate zone can be distinguished. *b*, Muscle from 20-d embryo following paralysis with TTX from 17 d onwards. Endplate clusters are present near the centre of the muscle, with extrajunctional clusters near the fibre ends. *c*, Muscle from 19-d embryo following paralysis with TTX from 16 d onwards. There is no clear area between endplate clusters and extrajunctional clusters. Individual silver grains cannot clearly be resolved in these low-power micrographs (scale bar, 500  $\mu$ m). *d* And *e*, receptor distribution on muscle fibres teased from 16 d–19 d TTX-treated muscle, to show that multiple clusters were present along the length of single muscle fibres. Scale bars 50  $\mu$ m. Pictures similar to those in *b*–*e* were obtained from muscles after  $\beta$ -bungarotoxin injections at 17 or 16 d, respectively.

with  $\beta$ -bungarotoxin at the same initial times. Paralysis during the period 16–19 d produced muscles in which junctional clusters could clearly be distinguished from extrajunctional clusters (Fig. 2*c*), but with no cluster-free regions of muscle membrane. Paralysis from 17–20 d gave rise to muscles with a clear area containing only diffusely distributed receptors between the junctional and extrajunctional clusters (Fig. 2*b*). The only distinction to be made between  $\beta$ -bungarotoxin-treated and TTX-treated muscles was in the size of the junctional clusters; for example 17–20 d TTX-treated muscles had junctional clusters with mean dimensions of  $13.98 \pm 0.34 \mu$ m, similar to those of 20 d controls. Extrajunctional clusters were  $7.46 \pm 0.14 \mu$ m in length.

Paralysis with TTX from 15–18 d produced muscles less comparable with  $\beta$ -bungarotoxin-treated tissues. The one control (water-filled capillary) embryo which survived from this

time was normal with respect both to gross development and to ACh receptor distribution, indicating that effects on treated embryos were due to the TTX and not to insertion of the capillary. Of three treated embryos which so far have survived, one was dwarfed and two appeared normal when examined at 18 d gestation. Muscle development was severely retarded, with myotubes only in the centre of the diaphragm muscles, surrounded by large areas of unfused myoblasts. After the TTX had been washed off, isolated muscles contracted in response to nerve stimulation. Junctional clusters of normal size ( $13.70 \pm 0.33 \mu$ m) were present, but there were few extrajunctional clusters.

Diaphragm muscles contracted in response to nerve stimulation at 15-d gestation, before clusters of ACh receptors could be resolved with our techniques. Intracellular recording from 15-d intercostal muscles (M. J. Dennis and A.J.H., unpublished)

showed that nerve stimulation produced endplate potentials in every muscle fibre tested (50/50), and that miniature endplate potentials at this age were much smaller than in 16-d muscles, despite similar resting potentials ( $>70$  mV) at both times. Nerve fibres are physically present in developing muscles before fusion of myoblasts into myotubes has begun<sup>11</sup>. Thus muscles contract in response to nerve impulses at least 6 h before ACh receptor clusters can be resolved. It is our impression that clusters first appear as distinct units, rather than growing by progressive aggregation of dispersed receptors. It is interesting to note that once an area of muscle has developed without receptor clusters they cannot appear there later, so that denervation leads only to an increase in the density of dispersed receptors in that region. That this is not simply a matter of time was shown by denervating rat intercostal muscles at birth, and examining muscles in which denervation was maintained for up to 4 weeks; extra-junctional clusters appeared only near the tendon ends of the muscle fibres, in regions which had developed since the time of denervation.

Neither destruction of the innervation nor paralysis of nerves and muscles in rat embryos prevented the formation of receptor clusters, and fusion of myoblasts into myotubes was only retarded and not arrested by these procedures. We conclude that, by evoking muscle contraction, innervation speeds the expression of a developmental programme inherent in myogenic cells for elongation and growth of myotubes and for the first appearance of ACh receptor clusters. The effects of electrical stimulation or of application of TTX to spontaneously contracting monocultures of myotubes in tissue culture are consistent with this description<sup>4</sup>. A specific inductive action<sup>12</sup> of the nerve terminal, exerted independently of electrical activity, must be postulated to regulate the positioning of the cluster under the nerve terminal<sup>5,13</sup> and for its progressive increase in size<sup>3</sup>. In the presence of a nerve terminal electrical activation of the muscle prevents the appearance of further receptor aggregates. TTX treatment over the period 15–18 d had an effect more drastic than denervation, perhaps by affecting spontaneous as well as nerve-induced muscle contractions, and so retarding muscle growth. If the appearance of extra-junctional clusters in denervated muscles is secondary to muscle growth, as seems likely (Fig. 2b), their apparently paradoxical absence from the 15–18-d treated muscles may be explained by the muscles being in a developmental stage reached by  $\beta$ -bungarotoxin-treated tissues at 16½ or 17 d. Further experiments are needed to clarify this point.

The only known action of TTX is to block the action potential mechanism in excitable tissues. Chronic local application to mature motor nerves causes prolonged paralysis but only partially blocks the trophic effect of the nerve on muscles<sup>14,15</sup>. The residual trophic action of the paralysed nerve may depend on materials carried by axonal transport<sup>16</sup>, although this is debatable<sup>17</sup>. Electrical stimulation of adult motoneurons increases the amount of proteins carried by axonal transport<sup>18</sup>, and as application of TTX to embryos blocked action potentials in motoneurone cell bodies as well as axons this might have reduced the rate of synthesis of the hypothetical trophic substances. Thus the argument made above for electrical activation being of primary significance in nervous regulation of embryonic muscle development is the most economical, but it is not definitive.

We thank J. J. Bray and R. G. Mills for instruction in their technique for chronic application of drugs from capillaries<sup>19</sup> and for <sup>125</sup>I-labelled  $\alpha$ -Naja toxin, and Katherine Hattersley for technical help. This work was supported by the New Zealand MRC.

## Composition and control of secretions from tracheal bronchial submucosal glands

TRACHEAL bronchial submucosal (TBS) glands are thought to supply a significant fraction of respiratory tract fluid (RTF)<sup>1</sup>, which is critically important in cleaning the airways of the lung. In the cleaning process, cilia in the tracheal bronchial tree continuously sweep the RTF, with debris, out of the lung. But abnormalities in the physicochemical properties of the RTF may impair this clearance, resulting in fluid stagnation, infection and obstruction of the airways. Unfortunately, because of the small size and inaccessibility of TBS glands and the difficulty in collecting their uncontaminated secretions, little is known about their physiology. We have developed methods for collecting and analysing secretions from single TBS glands of the cat *in vitro*, and we describe here the composition and control of the fluid secreted by these glands. We have found that the composition of the secreted fluids is very similar to that of the extracellular fluid and that secretion flow rates are influenced predominantly by  $\alpha$ -adrenergic and cholinergic agonists. In view of the well known exocrinopathy in the lethal genetic disease cystic fibrosis (CF)<sup>2</sup>, we believe these findings to have implications for pathological changes in the airways in this disease.

Tracheae were excised from seven mongrel cats anaesthetised with pentobarbital (35 mg per kg). Using a modification of a technique<sup>3</sup> for observing secretion *in vivo*, the tracheae were opened along the dorsal fold, and the epithelial surface was dried quickly with cotton sponges and a jet of freon-13 gas. The surface was coated immediately with water-saturated paraffin oil, and a segment of the trachea (about 1 cm<sup>2</sup>) was mounted in a chamber such that the serosal tissues were constantly bathed in Ringer solution which mimicked interstitial fluid (Table 1), while the epithelial surface remained covered with oil. Secretion was stimulated by adding appropriate concentrations of bethanechol (cholinergic agonist), methoxamine ( $\alpha$ -adrenergic agonist) and isoprenaline ( $\beta$ -adrenergic agonist) to the bath. Under a dissecting microscope, small droplets of secretory fluid were observed to form on the tracheal epithelial surface shortly after stimulation. Timed collections of droplets secreted from three to four glands were taken up between oil blocks in constant-bore capillaries (78  $\mu$ m inner diameter), and droplet volumes were measured for rate determinations usually over a period of about 5 min. The elemental chemical composition of each sample was assayed by microdroplet X-ray analysis for Na, K, Ca, Cl, S, and P (ref. 4).

Secretory rates reached maximal values about 10 min after the application of agonists, after which the rates generally declined (Fig. 1). Maximal rates as high as 20 nl per min per gland were induced but not sustained by bethanechol or methoxamine. Maximal secretory rates with  $10^{-5}$  M isoprenaline in the bath were generally less than 10% of the maximal rate induced by  $10^{-6}$  M bethanechol or  $10^{-5}$  M methoxamine (Fig. 1). Glands generally responded to stimulation for at least 5 h *in vitro*, but, probably due to variation in gland sizes, there was considerable variation in secretory rates between glands.

The composition of secretions was basically the same as that of the bath. There were no significant changes in the concentrations of any of the principal electrolytes (Na, Cl, K or Ca) as a function of the secretory rate or the nature of the applied stimulant (Table 1). Hence, if TBS glands normally secrete essentially isotonic fluids *in vivo* we conclude that, unlike most other exocrine glands, the cat TBS gland does not significantly modify the electrolyte composition of the primary fluid in the ductal region before it is excreted.

Fig. 1 A typical secretory rate response (ordinate) of a single TBS gland to increasing concentrations of bethanechol (BETH), isoprenaline (ISOP) and methoxamine (METH) in the bathing media. The time of addition of each drug at the indicated concentration is shown by the position of the inverted arrow relative to the abscissa. Rinsing was carried out by changing the bath to Ringer's solution (RCL). Concentrations, an order of magnitude higher than those shown, were examined in trials, but did not reveal noticeably higher maximal rates, even though rinsing times were increased.

However, a notable exception to this otherwise relatively constant composition is in the mean concentration of sulphur, which varied significantly depending on the nature of the stimulating agent. Methoxamine-stimulated secretions contained significantly less S (2.1 mM) than either bethanechol (3.2 mM;  $P < 0.025$ ) or isoprenaline (4.8 mM;  $P < 0.005$ ) stimulated secretions, but the difference between the mean concentration of S in bethanechol and isoprenaline stimulated secretions was not statistically significant ( $P < 0.1$ ). Sulphur concentration varied widely among glands (range 1–16 mM) and was inversely correlated with secretory rate (for individual glands, correlation coefficients ranged from  $-0.33$  to  $-0.82$ ).

Both the wide variation in the S concentration and the negative correlation with secretory rate indicate that S appears in the gland secretion by a route different from that of elements in the precursor fluid. Because isotopic S is taken up by TBS gland cells<sup>5</sup> and incorporated into the glycoprotein component of tracheal secretions<sup>6</sup>, mucus is the most probable additional source of S. If the concentration of S reflects the mucus content of the secretions, the data indicate that isoprenaline stimulates secretions with low flow rates but relatively high mucus content,

Table 1 Concentrations (mM) of the major inorganic elements in TBS gland secretions after stimulation with  $\alpha$ - and  $\beta$ -adrenergic and cholinergic agonists

	Na	Cl	K	Ca	P	S
Methoxamine ( $\alpha$ -adrenergic) $n \geq 35$	135 $\pm$ 1.7	119 $\pm$ 1.7	5.7 $\pm$ 0.18	0.6 $\pm$ 0.06	0.9 $\pm$ 0.11	2.1 $\pm$ 0.27
Bethanechol (cholinergic) $n \geq 13$	134 $\pm$ 2.1	124 $\pm$ 1.9	6.3 $\pm$ 0.28	0.7 $\pm$ 0.12	1.3 $\pm$ 0.14	3.2 $\pm$ 0.4
Isoprenaline ( $\beta$ -adrenergic) $n \geq 13$	141 $\pm$ 2.7	126 $\pm$ 2.5	5.7 $\pm$ 0.30	0.6 $\pm$ 0.08	1.1 $\pm$ 0.18	4.8 $\pm$ 1.09
Incubation	136	119	5.0	2.0	1.2	1.2

Except for S there was no statistically significant difference in the concentration of any element among secretions stimulated with the different agonists. Sulphur in methoxamine-stimulated secretions was significantly lower than S concentrations in the other two groups of secretions as determined by Student's *t*-test<sup>12</sup>. Errors are standard errors of the mean; the number of samples analysed was equal to or greater than *n*.

whereas methoxamine stimulates secretions of high flow rates but relatively low mucus content. Bethanechol stimulates secretions of both high flow rates and relatively high mucus content (Table 1, Fig. 1). In other exocrine glands such as the parotid, protein secretion is higher during  $\beta$ -adrenergic stimulation while flow rates are higher during  $\alpha$ -adrenergic stimulation<sup>7</sup>. Similarly, the rates and protein content are higher with cholinomimetic stimulation in the salivary gland, but the higher protein content may be due to  $\beta$ -adrenergic effects of the cholinergic agonist<sup>8</sup>.

The observation that different stimulatory drugs evoked distinct maximal secretory rates and different S (mucus) concentrations supports the view that the physical properties of the RTF may be regulated by combined sympathetic and parasympathetic controls<sup>5</sup>. If the autonomic nervous system controls the relative amounts of fluid and mucus, autonomic disturbances in CF<sup>9,10</sup> may produce abnormal volumes of secretions or abnormal concentrations of mucus which depress respiratory clearance mechanisms. This type of defect may explain why, although widely accepted, no defect in mucus production in this disease has been established<sup>11</sup>. Also, if there is no ductal modification of the precursor fluid, the defect in CF would seem to be basically a problem of secreting appropriate volumes and mucus concentrations.

In conclusion, cat TBS glands produce a secretion which is essentially isotonic, but which varies in S and possibly mucus content as a function of the nature or degree of stimulation. The results are consistent with the possibility that malfunctions in the TBS glands in CF may alter the properties of the RTF and thereby impair airway clearance, rendering the CF lung highly susceptible to infection and obstruction.

## Clues to the site of origin of the complementary image

PATTERNS of near-parallel black-and-white lines induce an anomalous state of the visual system, in which a superimposed test field of dynamic noise (such as the 'snowstorm' on a detuned TV receiver) seems to stream in directions roughly perpendicular to the inducing contours<sup>1</sup>. The illusory streamers form a 'complementary image' (CI) which for the stimulus of Fig. 1a comprises a family of wavy circles, as sketched by J. P. Wilson<sup>2</sup> in Fig. 1b. When two orthogonal gratings are superimposed, the streamers lie at 45° to both, as if the resulting bias obeys the rule of vector summation<sup>3</sup>. J. P. Wilson<sup>4</sup> has observed rudimentary signs of directional bias and streaming even at a single black/white contour; and M. E. Wilson<sup>5</sup>, using only simple pairs of test spots illuminated in sequence, found that the illusory 'phi' motion seen between the spots was enhanced for directions orthogonal to the contours of a superimposed grating. When the inducing pattern is presented to one eye and the noise field to the other, however, little or no CI is observed<sup>1,6</sup>. It has seemed logical<sup>1</sup> to attribute these phenomena to some form of adaptive cooperative activity among orientation-sensitive cells of the visual system, leading to a kind of 'simultaneous contrast' in the orientation domain, that is, a bias of the signalling system for motion and contour orientation in favour of the orientation(s) not present in the inducing stimulus.

Human observers can perceive contours outlined only by contrasts of texture or colour almost as readily as those due to differences in luminance. It would therefore help in locating the site of origin of the CI to know whether the system responsible can be directionally biased by patterns outlined only by contrasts of texture or colour. Hammond and I<sup>7,8</sup> have recently found that 'simple' cells in area 17 of cats, which respond briskly to a suitably orientated moving black bar, show no response to a similar (clearly recognisable) bar of random visual texture moving over a static textured background of the same mean luminance. Although the colour sensitivity of simple cells in area 17 of primates is still controversial<sup>9,10</sup>, it seems that most are also insensitive to boundaries outlined by colour contrast alone. Thus, if the CI could be induced by patterns of texture or colour contrast alone, this would suggest that it originated in a system not dependent on simple cells for its input (unless human simple cells differed in this respect from those of cat and monkey). If, however, induction of the CI required the patterns to be outlined by luminance contrast, this would point to the simple-cell system as the likely site of origin.

In the first experiment, a 60-ray pattern 12 cm in diameter, similar to Fig. 1a, was cut from white paper and placed over the screen of a detuned TV receiver generating dynamic visual noise. The paper pattern was front-lit at a luminance of 30 cd m<sup>-2</sup>. With the mean luminance of the TV display either higher or lower than that of the paper pattern, the normal CI was clearly visible in the noise. When the mean luminance was adjusted to the same level (30 cd m<sup>-2</sup>), however, the CI disappeared, although the white ray pattern remained clearly perceptible by contrast with the dynamic noise between its spokes. (Some 60 observers have confirmed these findings).

An analogous experiment was then carried out using patterns outlined by colour contrast. A pair of conventional 100-W slide projectors with red and green filters (Cinemoid nos 14 and 24) were used in conjunction with a mixer cube to project on to the noise-filled TV screen the same 60-ray figure outlined at ~20 cd m<sup>-2</sup> in red and green. The mean luminance of the (white) noise field alone was adjustable for optimum effect. When the luminances of the interleaved red and green rays were matched the CI was absent or much reduced for all of five observers, although with the red or green rays alone (that is, one projector switched off) it was clearly visible.

**Fig. 1** a, The stimulus used for the production of a CI. b, The family of wavy circles obtained.

It therefore seems that the anomalous physiological condition responsible for the CI arises not at the level of the pattern-recognition system *per se*, but at an earlier stage of visual information processing which is specifically sensitive to contrasts of luminance, although not of texture or (perhaps) colour. The absence of significant interocular transfer suggests a location in the monocular visual sub-system. The parallel with the preferences shown by simple cells in area 17 of cats and monkeys points to these cells, or others dependent on them, as likely candidates.

I thank my wife and M. G. Forster for assistance.

## Contribution to reproductive effort by photosynthesis of flowers and fruits

REPRODUCTION is often a lethal or semi-lethal activity, and for iteroparous plants it is often possible to show that reproduction has costs that are expressed in a reduced growth rate and/or an increased death rate<sup>1</sup>. Attempts have been made to compare life history patterns in flowering plants by measuring the fraction of a plant's annual dry matter production (or calorific value) that is allocated to reproduction (for example refs 2–4). The assumption is that the reproductive parts represent a cost in energy or materials. Clearly mineral nutrients and water must be gained by the reproductive structures from the remainder of the plant, but this is not necessarily true for the energetic and carbon economy of the reproductive structures. Many flowers and fruits are green and a fraction of the energy and carbon might be obtained by direct photosynthesis within these structures. This might be especially important during embryo growth if carpels and other organs that remain attached after flowering are green. In such cases the conventional estimation of reproductive effort (dividing seed weight by plant weight) would be incorrect and comparison of life history patterns and their evolutionary meaning would be invalid. There are reports of significant contributions of *in situ* photosynthesis in flower and seeds to their growth. Biscoe *et al.* have estimated that 47% of the carbon required for seed production in barley is provided by photosynthesis of reproductive and immediately adjacent plant structures<sup>5</sup>. Bazzaz and Carlson have shown that in the annual weed *Ambrosia trifida* L., net photosynthesis by reproductive structures amounts to 41 and 51%, respectively, of the carbon required for male and female inflorescences<sup>6</sup>. Here we report an analysis of the carbon budget of reproduction for 15 temperate deciduous trees. The budget was determined by measuring the weight, photosynthesis and dark respiration of flowers or inflorescences from bud break until seed maturity.

Inflorescences, flowers or fruits with a 3–5-cm piece of stem were excised from plants, sealed in vials containing water, and the rate of CO<sub>2</sub> exchange of the inflorescence was determined, first in the light (700 µE m<sup>-2</sup> s<sup>-1</sup>) and then in the dark

(1 µE m<sup>-2</sup> s<sup>-1</sup>) (ref. 7). Carbon dioxide exchange was measured at an air temperature equal to the mean daily maximum temperature (calculated from 20-yr summaries of weather data for Morrow Plot, Urbana, Illinois) for each day in which measurements were taken.

The data for photosynthetic and dark respiration rates were fitted by least squares regression to exponential, logarithmic and power univariate expressions with time as the independent variable. The expression with the largest coefficient of determination (*r*<sup>2</sup>) was chosen to represent the rate of CO<sub>2</sub> exchange throughout reproductive development.

Weight data were fitted to a linear form of two different functions and the one with the highest *r*<sup>2</sup> was chosen to represent weight gain for that species. One of the functions used had both a lower and an upper asymptote

$$W = \frac{K}{1 + e^{c-bt}} \quad (1)$$

and the other had only an upper asymptote

$$W = K(1 - e^{c-bt}) \quad (2)$$

where *W* = weight of flower or inflorescence in mg, *K* = weight at maturity in mg, *e* = base of natural logarithms, *c* = a constant of integration determining the position of the curve relative to the origin, *b* = the capacity for increase in units of mg/t, and *t* = time in days since 14 March. In fitting data to equations (1) and (2), *K* was estimated by trial and error to maximise *r*<sup>2</sup>. A carbon budget was constructed as described previously<sup>6</sup>.

There were three general types of weight gain curve for reproductive structures (Fig. 1). A continuous form of equation (1) represented the best expression for growth in 11 species (Table 1) and is exemplified by *Platanus occidentalis*. Equation (2) was the best expression for reproductive growth for two species represented by *Acer saccharum* (Fig. 1b). The third type of reproductive growth is the split or two-phase form of equation (1) as found for *Liriodendron tulipifera* and *Magnolia stellata* (Fig. 1a). Large showy petals were formed during the first part of reproductive development but fell off by about day 65, causing a sharp decrease in weight. Other species also lost some floral parts during development but that did not alter the smooth character of the growth curve.

The pattern of development described by equations (1) and (2) may reflect important differences in the metabolic cost of

reproduction. Systems that are well described by equation (1) apparently lack an initial mass transfer of carbohydrate from the plant into the developing reproductive structure but those described by equation (2) seem to have such a transfer.

The amount of carbon supplied from *in situ* photosynthesis to the total carbon required for production of mature seed varied from 64.5% for *Acer platanoides* to 2.3% for *Quercus macrocarpa*.

The results suggest that flowers and fruits should not be regarded simply as a cost to the carbon budget of the rest of the plant. Clearly in some cases green flowers may be sufficiently active photosynthetically to pay a major fraction of the energetic and carbon cost of their own structure and that of the ripened seed. Thus it is misleading to express reproductive yield as if it is the product of leaf photosynthesis. One implication of this finding is that the energetic costs to an animal-pollinated plant with showy non-green flowers may be two-fold—both the carbon cost of making the structure and the costs of sacrificing its potential photosynthetic ability. The sharp break in the floral growth curves of the *Liriodendron*-type emphasises this point. Furthermore, in the improvement of crop plants, we should perhaps consider the extent to which the photosynthetic activity of floral structures might be improved.

## Is compensatory growth a complicating factor in mouse teratology?

METHODS developed in an attempt to optimise the chances of identifying a teratogen generally involve the administration of the compound to a pregnant female in a number of ways, followed by autopsy about 24 h before parturition. This system maximises the period during which abnormalities may develop and circumvents loss by cannibalisation of dead or deformed newborn animals by their mother. The methodology is simple and efficient but provides no information about the immediate response of the embryo to the drug and any capability it may have for regulation or recovery from damage. Thus developmental disturbances could pass unnoticed. However, the damage, for example behavioural or reproductive abnormality, may manifest itself postnatally, and this has recently aroused some concern<sup>1,2</sup>. We report here on the mode of action of a known teratogen, mitomycin C (MMC) on mouse embryos. In rodents this antibiotic is teratogenic at high doses. In rats the LD<sub>50</sub> and teratogenic dose seem to coincide, but for mice these figures may differ considerably<sup>3–5</sup>. Abnormalities reported include exencephaly, spina bifida<sup>6</sup>, skeletal and other non-nervous system defects<sup>7</sup>. The frequency of abnormality and dose response is strain dependent in mice. We know of no reports on the immediate response of mouse embryos to MMC and of only one on the postnatal development of mice exposed to the drug *in utero* in mid-gestation<sup>8</sup>. Our results indicate that, during early organogenesis stages, the mouse embryo has a remarkable capacity for recovery from severe damage and developmental retardation induced during primitive-streak stages, when drugs were thought more likely to be lethal than teratogenic.

Random bred Q strain mice were used. Pregnant females received a single injection of MMC intraperitoneally 6½ or 7 d postcoitum (p.c.). Two doses were used, 100 and 150 µg per mouse (~4 and 6 mg per kg). There were no noticeable differences in response to the two doses, so data have been pooled. In this strain the primitive streak begins to form between 6½ and 6¾ d p.c. Initially autopsies were done at 7½ and 8½ d p.c.

**Table 1** Cell numbers and mitotic activity in control and MMC-treated 7½-d embryos

<i>n</i>		Control 6	MMC 5

	Endoderm	1,019 ± 57	374 ± 33
M/A index	Ectoderm	3.9 ± 0.2	12.5 ± 1.5
	Mesoderm	1.9 ± 0.2	5.2 ± 0.7
	Endoderm	4.5 ± 0.6	6.1 ± 0.7

Camera lucida drawings were made of transverse sections and tissue volumes computed from planimeter measurements of tissue areas. Cell numbers were then calculated from a knowledge of cell volume<sup>13</sup>.

but were subsequently extended to various other time points, including postnatal development.

At 7½ d MMC embryos were morphologically normal but very small (Fig. 1a, b). On the other hand, the extra-embryonic regions of the egg cylinder are of normal size, but in some the mesodermal layer of the exo-coelom is incomplete. Serial reconstructions of embryos show that in MMC embryos cell numbers are reduced to about 14% of normal but that mitotic activity is much higher (Table 1). In a study of the time course of development following MMC injection at 7 d p.c. (zero time) dead cells (pycnotic granules) are observed at 1½ h and are most abundant at 6 h. Mitotic activity falls to its lowest at 6 h. The high mitotic activity in 7½-d MMC embryos seems therefore to reflect accelerated, compensatory growth in the embryo.

At 8½ d MMC embryos are still small and are now morphologically retarded (Fig. 1c, d). Headfolds are usually very small, or absent, the anterior end of the embryo usually being at the neural plate stage, that is, about 12 h retarded. In some embryos the posterior end seems more advanced, with a well developed allantois and occasionally with an early hind gut and one or two somites. The mitotic index is high throughout the embryo. Control embryos at this stage have raised head folds, neuromeres, up to seven pairs of somites, a beating heart, and fore and hind gut, and chorio-allantoic fusion is complete.

We initially thought that MMC embryos would die, but at 10½ d, although still small, they were almost normal. Head development showed no outward sign of retardation, but somite numbers were low (29 against 35 pairs in controls) and hind limb bud development was late in many. The course of development of MMC embryos is shown in Table 2. By 13½ d the only evidence for retardation in MMC embryos is that the mean fetal weight is significantly low (126 ± 3.0 mg, 5 litters, 42 embryos in MMC mice against 143 ± 3.4 mg, 4 litters, 42 embryos in controls,  $t = 3.1$   $P < 0.0025$ ). Abnormalities were found in one litter. Among the 10 embryos there were four cases of microphthalmia and one cleft face. There were no abnormalities in controls.

Litter sizes were a little lower in MMC-treated females, all embryo mortality occurring before 13½ d of gestation. Seventeen control litters averaged 10.9 implants and 3.2% mortality, whereas in 72 MMC litters these figures were 10.7 and 10.0%.

At birth MMC newborn animals were not noticeably small but were not weighed: 6% were stillborn. In 14 litters (mean size 8.0) microphthalmia was seen in 5, in 26% of all 14-d-old mice. No other abnormalities were seen. Growth was often slow and mortality was extremely high (25%, 53% and 64% being dead at 7 d, 14 d and 21 d, respectively). Of 14-d survivors, 50% were runted. Two entire 14-d litters had the appearance of 8-d-old mice, none had its eyes open. Only 30% (29 mice) were successfully weaned.

All runts and many of their larger littermates showed motor defects. Gait was slow and stumbling and many trembled violently. Most were reluctant to move and some were easily knocked over and took 5–10 s to get back on their feet. One extreme case would lie on its side for 30 s or more before moving.

Most runts and those with the worst motor defects died before weaning. Wilson razor blade slices were made of four severely affected 14-d mice but no internal abnormalities were found, all organs being present, correctly located, of normal proportions and with no noticeably enlarged cavities. Survivors generally seemed normal at weaning.

Fertility is low. All 29 survivors were test-mated to normal Q mice of proven fertility. All 18 males mated but 8 gave sterile plugs. Histological examination revealed small testes deficient in germ cells, many tubules containing only Sertoli cells. Of the 11 females 2 were sterile; both had small ovaries with about half as many follicles as controls, and one also developed motor defects after weaning. Histological examination of MMC embryos between 7½ and 11½ d in which alkaline phosphatase-positive primordial germ cells (PGC) were counted indicated severe depletion of PGCs in all MMC embryos up to 9½ d. Subsequently about half the embryos show good recovery of germ cell numbers. Migration of PGCs was retarded, even if allowance was made for the general developmental retardation.

Several other studies have used doses of MMC similar to or higher than those used here but none has started as early in pregnancy<sup>9–11</sup>. They cover the period 7½–15 d p.c.; all report high levels of induced abnormalities, up to 90% of females presenting abnormal fetuses and 64% of fetuses being affected. These figures agree well with the frequency of severe developmental retardation seen in our 8½-d embryos (100% of females present, up to 75% of fetuses affected), but do not correspond at all with the level of abnormality seen at late gestation. As all our experiments commence in pre-organogenesis stages this is perhaps not surprising. What our study does show is that the mouse embryo can withstand a major disturbance in its early development and recover to such an extent that structural abnormalities rarely emerge.

The frequency and nature of abnormality found in our 13½-d embryos gives little suggestion of the profound effects on post-

**Table 2** The course of development of embryos exposed to MMC at 6½ or 7 d postcoitum

Age at autopsy (d p.c.)	Age at injection	% of embryos showing:

No headfold or somite development has occurred.

natal development and fertility, of MMC applied during pre-organogenesis stages. However, MMC-induced reduction in fertility has been reported to follow treatment given in mid-gestation<sup>8</sup>.

We have shown that the mouse embryo can be reduced to around 10% of its normal size at a time when it is about to begin organogenesis, but is nearly normal again before that phase of development is complete. Much of this regulation, especially morphogenesis, is accomplished within 48 h of the damage being inflicted. In particular, the formation of the brain and head seems to be achieved in about half the time it normally takes. During this period of accelerated development the embryo may be more susceptible to damage which would normally be trivial. It may explain, for instance, why some teratogens have their severest effect when administered as a series of small doses rather than as a single large dose<sup>5,12</sup>, a possibility not considered by Wilson in a discussion of the complications introduced by repeated dosing<sup>5</sup>.

## Hybrid sterility in meadowlarks

THE eastern meadowlark (*Sturnella magna*) and western meadowlark (*S. neglecta*) are sibling species of songbirds in secondary contact throughout a narrow zone of sympatry in central North America<sup>1–3</sup>. Field studies suggest that specific differences in vocalisations are the principal isolating mechanism and that hybridisation is limited in extent and possibly restricted to regions of recent contact<sup>4–7</sup>. The incidence of hybridisation is difficult to determine, however, due to their similar appearance, and there is uncertainty as to the recognition of some hybrids of known parentage<sup>7</sup>. Multivariate analysis alone offers no additional resolution to the problem<sup>8</sup>. A programme to breed and hybridise meadowlarks in captivity is one approach to determining the viability and fertility of hybrids. The difficulties inherent in the technique and the time required to amass adequate samples have precluded its use among avian systematists, with the exception of those working on some game species<sup>9,10</sup>. However, I now report that between 1966 and 1978 I was successful in inducing 25 captive meadowlarks to pair and produce 44 clutches of 158 eggs. Mixed matings among non-hybrids resulted in 90% fertility, not significantly different from the 87% fertility among eggs from pure matings, whereas the fertility of eggs from pairing of hybrids was only 10%. All eggs resulting from pairing the one surviving backcross hybrid were infertile.

Indicative of the infertility of my hybrid meadowlarks is the performance of three siblings produced in my aviary in 1975, from a mixed pairing of a male *S. magna* and a female *S. neglecta*. The three hybrids, two males and a female, did not breed at 1 yr of age, although paired with experienced mates. In 1977 the female hybrid was paired with a male *S. neglecta* that had bred successfully the previous year. She built a typical meadowlark nest, laid a clutch of four eggs, and incubated with normal attentiveness. On the eighth day of incubation I determined that all eggs were infertile. The male *S. neglecta* demonstrated his continued fertility by breeding successfully the following year. One of the male hybrids was paired in 1977 with a female *S. neglecta* that had bred successfully 2 yr earlier. She laid a clutch of four eggs determined to be infertile after 6 days of normal incubation. Also in 1977, the second male hybrid was paired with a 2-yr-old female *S. magna*, who laid a clutch of three eggs that proved to be infertile after 10 days of normal incubation. This female laid fertile eggs the following year in a mixed pairing with a male *S. neglecta*.

My most extensive and convincing data were accumulated on a male hybrid produced from a mixed pairing of a male *S. neglecta* and a female *S. magna* in 1966 (the first meadowlark ever produced in an aviary and raised to maturity). At 1 yr of age he was backcrossed with his mother, who laid a clutch of four eggs that proved to be infertile after 11 days of normal incubation. At 2 yr, he was backcrossed again with his mother, who laid three clutches and a total of seven infertile eggs. During that same season he was paired with two different hybrid females. These crosses of F<sub>1</sub>'s resulted in three clutches and a total of 12 infertile eggs. In 1971, at 5 yr of age, he was paired with a female *S. neglecta*, a proven breeder who laid fertile eggs in a mixed pairing that same year and continued to produce fertile eggs over the two ensuing years. This backcross resulted in a clutch of four infertile eggs incubated normally for at least 8 days.

The only fertile eggs from a pairing of a hybrid were laid by a female hybrid produced in the wild near Poughkeepsie, New York, from a mixed pairing between a male *S. neglecta* and a female *S. magna*<sup>7</sup>. This female hybrid was first successfully paired in 1968, when pairings with a male hybrid produced two clutches and a total of eight infertile eggs. In 1971, at 9 yr of age, she produced two fertile clutches: one of four eggs in a pairing with a male *S. neglecta*, and one of three eggs in a pairing with a male *S. magna*. However, in that same year she laid four infertile

eggs in a pairing with another male *S. neglecta* who had already bred successfully earlier in the season, and she laid a clutch of eggs in a second pairing with the male *S. magna* cited above, but the three eggs in this subsequent attempt proved to be infertile. A sibling female hybrid from the mixed pairing near Poughkeepsie was paired with one of my aviary-produced hybrids in 1968 and produced four infertile eggs. I was unable to establish breeding pairs with the other hybrids from Poughkeepsie.

Two of the backcross hybrids by the female hybrid cited above were hand-reared, but only one of these (a male, from W × F<sub>1</sub>WE) was subsequently involved in a successful pairing. When 2 yr of age this backcross hybrid male was paired first with a female *S. neglecta*, resulting in five infertile eggs, and later with a female *S. magna*, resulting in three infertile eggs. The female *S. neglecta* had bred successfully in my aviaries during each of the previous two years; the female *S. magna* produced fertile eggs before and after this unsuccessful pairing with the backcross hybrid.

The ease with which hybrids were produced from mixed pairings of captive birds, given no choice of mates, tells us little about the incidence of hybridisation of meadowlarks in the wild, where behavioural and ecological isolating mechanisms effectively limit mixed pairings throughout most of the zone of

sympatry. The sterility of the captive hybrids is significant, however, and suggests that when infrequent hybridisation does occur in natural populations, the hybrids are at a disadvantage and are selected against, a conclusion that had been suggested earlier by Rohwer's multivariate analysis of specimens from a region of sympatry<sup>8</sup>. The causal factors for the sterility are as yet unknown, but apply to hybrids of both sexes and to hybrids resulting from both categories of mixed pairings. Efforts to find abnormalities in the chromosomes of the hybrids have thus far been unsuccessful. The reduction in fertility is not accompanied by an obvious reduction in viability, for the captive hybrids appeared to be as healthy and vigorous as other captives.

I thank the following for assistance in maintaining the captive birds: Mrs Vicky Lanyon, the late Edward Szalay (who was superintendent of the Kalbfleisch Field Research Station) and James Mansky (current superintendent of the station).

Backcross hybrid × E	0/3	0/3	0
All pairings of hybrids		7/67	0.10

Earlier attempts to breed meadowlarks failed, presumably because the flight pens were too small and offered an insufficient area of natural sod for nesting substrate<sup>7</sup>. Ultimately I resorted to aviaries located in a grassland habitat at the American Museum of Natural History's Kalbfleisch Field Research Station at Huntington, New York, that measured 12.2 × 4.9 × 2.7 m, thus providing 60 m<sup>2</sup> of sod per breeding pair and ample unobstructed space to permit the aerial components of courtship. The sources of the breeding stock were as follows: seven *S. magna* captured in New York and New Jersey (three as adults and four as nestlings); five *S. neglecta* captured as adults in California; four *S. neglecta* produced in my aviaries from pairings of the California birds; one *S. neglecta* trapped as a breeding adult near Poughkeepsie, New York<sup>7</sup>; six hybrids produced in captivity from the foregoing stock, and two hybrids produced naturally near Poughkeepsie, New York<sup>7</sup>. Mixed pairings were as readily achieved in the flight pens as were pure pairings. No choice experiments were conducted. Whenever possible hybrids were paired with mates known to have bred successfully to maximise the significance of the performance of the hybrids. Fertility of eggs was established by candling after a minimum of four days of incubation, when the embryos and air sacs are clearly visible.

\* This clutch involved a male in at least its tenth year of age (1978) that bred successfully between 1970 and 1975; he was not paired with hybrids after 1975.

† These eggs were laid by the same female F<sub>1</sub> hybrid and were the only fertile eggs produced by a hybrid; four other clutches (15 eggs) produced by this hybrid were infertile.

## Arena of technological policy

Dorothy Nelkin

*Directing Technology.* Edited by R. Johnston and P. Gummert. Pp. 271. (Croom Helm: London, 1979.) £10.95.

BELIEF in the efficacy of technological progress is increasingly tempered by awareness of its ironies. Technological 'improvements' may cause disastrous environmental problems: drugs to stimulate the growth of beef cattle may cause cancer; 'efficient' industrial processes may threaten the health of workers; beneficial biomedical research may be done at the expense of human subjects; and a new airport may turn a neighbourhood into a sonic garbage dump. Even efforts to control technology may impose inequities, as new standards and regulations pit the quality of life against economic growth and the expectation of progress and prosperity. Indeed, the public policy discourse on directing technology has changed remarkably in the past ten years. How to promote and utilise technology for socially useful ends remains an important but no longer central issue; attention has shifted to a greater emphasis on ways of assessing and controlling potentially undesirable impacts.

*Directing Technology* is a book of thirteen essays edited by Ron Johnston and Philip Gummert, both from the Department of Liberal Studies in Science at the University of Manchester. The essays address the two thrusts of government involvement in the direction of technology: promotion through the encouragement of research and development, and control through regulation. Government intervention has increased in recent years, fostered by the growth and the scale of public investment in technology, by the importance of technology in international economics and politics, and by the increase in public criticism and concern. Various patterns of government promotion of technology through encouraging research and development are explored in six case studies in the

first part of the volume. They include cases in Western Europe (Keith Pavitt), Canada (Ian Chapman) and Great Britain (Philip Gummert). Examples are drawn from specific industries: nuclear power (Roger Williams), aviation (John Hartland and Michael Gibbon), and motor vehicles (Peter Stubbs).

The second half of the book focuses on mechanisms of control. The focus is primarily on the problem of safety, with chapters on the regulation of the automobile industry (Judith Reppy), on the environmental impacts of technology (Dave Ewa and Harry Rothman), on pesticides (Brendan Gillespie), and on recombinant DNA (Edward Yoxen). Various mechanisms of control are discussed in this section: technology assessment (Michael Gibbons) and the role of parliaments (John Hartland).

The book concludes with a most interesting article by Geoffrey Price, which—perhaps deliberately—serves as a critique of the entire volume. Price observes that policies for promotion and control of technology express social goals and priorities:

The differing approaches to the control of technology are themselves an expression of the basic assumptions made within different political traditions about the coordination of general social goals with the detailed activities needed to attain them. In short, approaches to the regulation of technology are themselves particular instances of the political assumptions which articulate a given society—whether they be those of centralised planning, Burkean conservative liberalism, or radical communitarianism.

Price goes on to argue, as I would, for more overt recognition of the political context of decision-making concerning the direction of technology. The political assumptions underlying technological decisions are often unstated, because it is convenient to maintain an image of neutral technology. But clearly decisions about promotion and control have significant social and political consequences. They may effect employment, the distribution of income,

or occupational health and safety. The collaboration between industry and government discussed throughout this volume may have serious political implications for the ability to control technology, as the functions of promotion and control necessarily come into conflict. Can we talk these days of directing technology without discussing the problems of scientific research as well? Can we talk about the government's role in the promotion of technology without dealing with the contradiction between its efforts to promote as well as to control?

Although this book is a very useful and timely collection of articles, I wish the editors had presented a detailed and critical analysis of such politically controversial problems. Several of the authors touch on political issues; the declining capacity of parliament to influence technology, or the secrecy of government institutions in dealing with the problem of pesticides. But, for the most part, the articles are relatively bloodless and bland. It is as if decisions in this highly political arena of technology policy—political in the sense of its consequences for the distribution of costs and benefits—occur in an ideological vacuum.

One way to approach these political assumptions would be to develop the comparisons implicit in the essays. Different countries approach common technological problems in different ways depending on political expectations and cultural styles. Comparative analysis can reveal assumptions underlying decision-making processes and they can suggest a wider range of policy options. A lack of comparative analysis more generally marks the field of science and technology policy. This book, with its case-studies from different countries, at least provides us with the opportunity. □

Dorothy Nelkin is a Professor in the Program on Science, Technology and Society at Cornell University, Ithaca, New York.

## Speculations on micromolecular evolution

*The Genetic Mechanism and the Origin of Life.* By L. S. Dillon. Pp. 563. (Plenum: New York and London, 1978.)

I FOUND this to be a strange book. The list of almost 3,100 references occupies 127 of its 562 pages. This does not include the space in the text occupied by citations; I counted 23 on one page. Obviously, only perfunctory mention can be made of most articles to which the citations refer. An analogy to describe the organisation of the first five chapters is that it seemed as if the author had been out in the fields with a butterfly net, industriously scooping up insects, which he sets before us in a display bewildering in its variety. His collection of topics includes everything from the origin of life, to the complete two-dimensional structure of MS-2 RNA, and the amino acid sequences of six calf-thymus and sea-urchin histones.

After this *tour-de-force*, the author proceeds to invent new theories from the stepwise evolutionary formulation of larger amino acids from smaller ones, such as alanine from glycine, and valine from aspartic acid. He says, for example, "In the author's laboratory, continuous bubbling of CO<sub>2</sub> through a 0.1 [sic] aqueous solution of alanine at ambient and elevated temperatures for a week failed to produce any detectable aspartic acid (Dillon, unpublished)", but he doesn't give up; he next says, "Hence, the addition can probably be made only through enzymatic mediation". He does not mention that aspartic acid is formed biologically by transamination, but not from alanine. Grandiose but unrealistic schemes are also set forth for "chemical evolution" of lysine, isoleucine and other amino acids from aspartic acid.

In chapter 7, Dillon proceeds to take sequences of tRNAs apart into small pieces and put them together again. He says that the absence of unmodified adenosine from the first site in anticodons is included in constraints which "to the author's knowledge . . . have not been previously noted in the literature". Actually, this is a well-known characteristic and has a familiar explanation, not mentioned by Dillon. Adenosine in the first position of anticodons is deaminated to inosine, (*Biochim. Biophys. Acta*, **213**, 352, 1970), which wobble-pairs with three different bases. The incorrect statement is made on p296 that "the triplet -CAA is consistently present at the 3'-terminus of the molecule" of tRNA.

The next chapter, on "tRNA evolution", attempts at great lengths to construct a phylogeny by comparing base sequences of various arms of tRNA molecules. Such a procedure is at variance with results obtained by aligning and comparing the complete sequences of tRNA molecules (*J. Molec. Biol.* **78**, 91; 1973), a method which shows that sequence changes have been so extensive as to obscure any phylogenetic relationship of nearly all tRNAs except for a few closely related pairs.

In chapter 9, Dillon goes butterfly-collecting for odds and ends among the structures of viruses. At one point he briefly notes, but does not describe, the "blocked complex 5'-terminal struc-

ture" in reovirus and polyhedrosis virus RNA, discovered by Miura *et al.* (p402). This is, of course, the "cap" of eukaryotic mRNA, an appendage which Dillon (p131) strangely ignored in describing the structure of eukaryotic mRNA. The book concludes (chapter 10) with highly imaginative (or imaginary) and grandiose scenarios for the origin of life, including schemes for the stepwise evolution of small viruses into large ones. The voluminous bibliography, following chapter 10, is probably the most useful feature of the book.

## Protein phosphorylation

*Cyclic Nucleotides, Phosphorylated Proteins, and Neuronal Function.* Distinguished Lecture Series of the Society of General Physiologists. Vol. 1. By P. Greengard. Pp. 124. (Raven: New York, 1978.) \$15.60.

IN this slim volume, Professor Greengard expounds his theory that protein phosphorylation is the final common pathway that mediates the biological effects of a wide variety of regulatory agents in addition to those that are known to act through cyclic AMP. It is really an extension of the 'second messenger' theory of cyclic AMP function, in that protein phosphorylation is depicted as the immediate and physiologically important result of increased cyclic AMP levels. However, Professor Greengard is nothing if not catholic in his enthusiasm for protein phosphorylation, and the actions of steroid and peptide hormones, insulin, interferon, all the neurotransmitters (excepting acetylcholine at nicotinic synapses) as well as the diverse effects of calcium ions are all envisaged by him as proceeding by this mechanism.

One's unease develops as the list increases; can the expression of all this biological diversity really be channelled through the simple phosphorylation of protein? It is clear that the regulation of glycolysis proceeds by cyclic AMP-induced protein phosphorylation. Other cases exist, but the argument from the particular to the general is not well founded. The mere correlation of varied cyclic nucleotides with protein phosphorylation in various circumstances is necessary but not sufficient to demonstrate it. It may be that protein phosphorylation is a side-effect of increased cyclic nucleotide levels rather than a mandatory stage in the expression of

their regulatory activity.

And even if protein phosphorylation was a mandatory stage, does this tell us much about the processes anyway? After all even if the theory were true, the important questions surely are; what proteins in each individual case are phosphorylated and how does this affect their physiological activity? Professor Greengard would probably agree that these questions are important and protest that he is merely proposing a working hypothesis for the detailed investigation of individual cases. But the trouble is that protein phosphorylation as a working hypothesis is so general and vague that it does not really help us formulate specific questions about regulatory mechanisms.

I turn now to the particular role of protein phosphorylation in neuronal and synaptic activity, Professor Greengard's special interest. He has proposed a scheme whereby a neurotransmitter (presumably the author has noradrenaline in mind, though it is not specified) is bound to its postsynaptic receptor and activates adenyl cyclase; this stimulates protein phosphorylation which causes a permeability change and thus a change in the membrane potential. Now, as Professor Greengard shows, the phosphorylative and enzymic activities prescribed by the scheme are found in the synaptic region but it is by no means clear that phosphorylation of the membrane protein causes the membrane conductance change that is known to be caused by transmitter action. The best experimental evidence that the author can offer is that isoproterenol (known to cause an increase in cyclic AMP) causes in turkey erythrocytes an increase in sodium influx, and protein phosphorylation, the dose- and time-response curves of which are similar. There are various correlations but none distinguishes between protein phosphorylation being a result of an increased ion flux rather

# Endorphins in Mental Health Research

Edited by Earl Usdin, William E. Bunney Jr. and Nathan S. Kline

This collection of papers provides an invaluable account of the current state of research in this new field of neuroscience. The vital issues covered are bound to stimulate a renewed controversy and further research activity - both from those already directly involved and from those who feel that they cannot ignore the increasing relevance of endorphins to their own work.

## Oxford University Press

### Disorder in Crystals

N. G. Parsonage and L. A. K. Staveley

This book surveys present knowledge of positional disorder, orientational disorder, and magnetic disorder in stoichiometric crystals, and therefore deals with the nature and interpretation of order-disorder transitions. The relevant thermodynamics and statistical mechanics are discussed, and experimental methods for studying disorder are reviewed. £28 *International Series of Monographs on Chemistry*

### Methods in Electromagnetic Wave Propagation

D. S. Jones

There has been considerable research into the problems of the propagation of electromagnetic waves during the past twenty years. This book deals with the analytical and numerical methods which have been developed. The book will be valuable to graduate students of applied mathematics and electrical engineering interested in the problems of radiating, transmitting, and receiving electromagnetic waves. It includes numerous exercises. £22.50 *Oxford Engineering Science Series*

### The Mechanics of the Circulation

C. G. Caro, T. J. Pedley, R. C. Schroter, and W. A. Seed

This book, first published in hard covers in 1978, sets out to explain in physical terms many aspects of circulatory function, both normal and abnormal. 'The book is a well-compiled production; the photographs and diagrams are superb and easy to follow. . . . It will be useful to undergraduates in physiology and biophysics.' *British Medical Journal*. Illustrated paper covers £11 *Oxford Medical Publications*

### The Numbers Game

Statistics for Psychology  
Joan Gay Snodgrass

This book describes a conceptual approach to the subject of statistics by describing the concepts underlying statistical methods with abundant use of examples drawn from the psychological literature. It also provides a practical handbook of statistical methods to cover the more complicated techniques necessary for the analysis of typical experiments. The hard-cover edition remains available at £11. Paper covers £5.95

## Plant Strategies and Vegetation Processes

by **J.P. Grime**, *Unit of Comparative Plant Ecology (NERC), Department of Botany, University of Sheffield.*

The purpose of this book is to distil from the wealth of theory and evidence available to plant ecologists, a succinct description of the way in which vegetation functions and is caused to vary in composition from place to place and with the passage of time.

The method which is used involves the recognition of the major adaptive strategies in plants, followed by an analysis of the role of strategies in the processes which control the structure, dynamics and species composition of vegetation.

The concept of strategies is applied systematically to a wide range of plant and criteria relating to both life-histories and physiology are employed. Special attention is devoted to regenerative strategies and on this subject, in particular, the book contains a considerable amount of hitherto unpublished data.

Although the central concern is to recognize unifying principles in plant ecology opportunities have been taken to extend the ideas to animals and to discuss some of the practical implications of the phenomena described.

## Arthropod Phylogeny with Special References to Insects

by **H.B. Boudreaux**, *Louisiana State University.*

The author elucidates the major evolutionary pathways of the Phylum Arthropoda, based on the phylogenetic method of Hennig. Groupings are assembled so that each group is based on shared character states which can be considered to be derived from a ground plan, and further modified in each subgroup. Emphasis is on the discovery of derived character states that most probably had a common origin in an ancestral state.

## The Global Carbon Cycle: SCOPE 13

edited by **B. Bolin**, *Department of Meteorology, University of Stockholm;*

**E.T. Degens and S. Kempe**, *both of the Geological Paleontological Institute, University of Hamburg* and **P. Ketner**, *Department of Ecology, Agricultural University of Wageningen, Netherlands.*

SCOPE'S project on Biogeochemical Cycles has provided a forum to assess existing knowledge on the carbon cycle and to define fields of ignorance. The results and recommendations of a six day workshop with about fifty internationally renowned natural and social scientists participating, and a subsequent one year intensive study by a working group, have been laid down in SCOPE Report 13. Here, a comprehensive and well-balanced discussion is given on the many facets of the carbon cycle highlighting model calculations; sinks and sources of carbon; kinetics of transfer and exchange between the various carbon pools; the problem of the build-up of CO<sub>2</sub> in the earth's atmosphere; assessment of primary production on land and at sea; research priorities in the field of the carbon cycle; the impact of humans on the natural environment; recommendations to improve environmental quality. (SCOPE Series)

0471 02695 6 \$20.35/£9.50

## Hunger Disease: Studies by the Jewish Physicians in the Warsaw Ghetto

edited by **M. Winick**, *Columbia University College of Physicians and Surgeons.*

A translation from the Polish of a manuscript smuggled out of the Warsaw Ghetto that details studies performed by the resident Jewish physicians on patients suffering from Nazi-imposed starvation. Some of the findings were firsts in the medical literature and others remain unique today. Each chapter of the book is followed by extensive comments by the editor — bringing the information up-to-date and outlining the most recent findings in the particular area discussed. Topics include: clinical changes in adults; clinical changes in children; metabolic adaptations including carbohydrate and acid base metabolism; pressure, venous and arterial pressure, oxygen consumption, and cardiac work measurements; changes in the eye and in vision; changes in the blood and bone marrow; and pathologic anatomy. (Series: *Current Concepts in Nutrition Vol. 7*)

than its cause. I believe this to be crucial; but even if it were conceded it is a far cry from the permeability changes of the turkey erythrocyte membrane, measured in minutes, to that of the synapse measured in milliseconds. Indeed, the whole problem of timing is ignored by Professor Greengard. As it is proposed that the membrane conductance change results from the sequential action of two enzymes, it is surely incumbent on the author to show that the substrate concentration and enzyme activities are sufficient to enable protein phosphorylation to be fast enough to account for the speed of the permeability changes.

In another section Professor Greengard described his experiments in which calcium influx into synaptosomes causes a phosphorylation of a particular protein (protein I) that he has identi-

fied as being only present in the synaptic region. This is interesting, but he concludes (p77) "that calcium is a regulatory agent some of whose effects may be mediated by protein phosphorylation". It may; but these experiments have only demonstrated that protein phosphorylation is one of the many sequelae of depolarisation in the presence of calcium, which is not the same thing at all. And it is this type of reasoning which eventually alienates support from the author's general hypothesis; this is a pity, as the subject of protein phosphorylation, to which Professor Greengard has made distinguished contributions, deserves careful analysis without preconception as to its rôle.

**R. M. Marchbanks**

*R. M. Marchbanks is Senior Lecturer in the Department of Biochemistry at the Institute of Psychiatry, London, UK.*

## Photosynthetic bacteria

*The Photosynthetic Bacteria.* Edited by R. K. Clayton and W. R. Sistrom. Pp. 946. (Plenum: New York and London, 1979.)

THIS very ambitious book attempts to provide an overall review of the present state of knowledge on all aspects of the study of photosynthetic bacteria at the highest level. It contains review articles by experts in many fields reflecting the importance of photosynthetic bacteria as excellent "simple" systems for studies of photosynthesis, membrane biogenesis, heme and carotenoid biosynthesis, and so on. This encyclopaedic approach has advantages and disadvantages. The main advantage of this book is that it provides an enormous amount of basic information about photosynthetic bacteria in readily accessible form. It must therefore become an essential reference work for any laboratory doing research on these organisms. However, the book has a number of disadvantages which arise from the attempt to be completely comprehensive. Almost every topic is covered by two chapters by different authors. This results in considerable duplication of material, even to the extent of printing the same electron micrograph in two chapters, and of course in conflicting interpretations. The result is to make the book much larger and more difficult to use than is required by the subject.

A more serious problem is that the book is out of date. It would seem that many, although not all, of the

chapters were completed in 1975, with minor updating to 1977. Although this is not too important for much of the background information, it is disastrous for articles dealing with rapidly moving research areas. The problem is made worse by variations in the amount of updating authors have done, and the confusion of multiple chapters dealing with each subject. For example, the chapter on primary electron acceptors does not mention the role of bacteriopheophytin in the reaction centre, because, as the author states, it was written in 1975 before this work was published. The work is in fact described in varying detail in three other chapters, although the chapter titles would not lead the uninitiated reader to look in them for this information.

The book is an excellent source of information on photosynthetic bacteria, but it must be used with a fairly critical attitude. It cannot therefore be recommended to non-specialists as a completely satisfactory dictionary of its subject.

**M. C. W. Evans**

● An English language edition of *Einstein* by Louis de Broglie, Louis Armand, Pierre-Henri Simon *et al.*, originally published in French by Hachette (Paris) in 1966, has now been published by Peebles Press International (New York) and David and Charles (Newton Abbot, UK) at £7.50.

● *The Runaway Universe* by Paul Davies (for review, see *Nature*, 272, 785; 1978) has been published in paperback as *Stardoom* (Fontana: London), price 95p.

## Capture-recapture methods

*Investigating Animal Abundance.* By M. Begon. Pp. 97. (Edward Arnold: London, 1979.) Paperback £3.95.

STUDYING the population dynamics or genetics of a natural population requires some knowledge of the changes in absolute population density over a period of time or between different locations. From this follows the opportunity to quantify the processes of birth and death, emigration and immigration. Adequate techniques for estimating population size are therefore of crucial importance to the study of natural populations.

Michael Begon has gathered together in a short volume a guide to a family of techniques for estimating absolute population size, all involving the mark, release and recapture of individuals from a population. These techniques (for example, Lincoln Index, Bailey's Triple Catch, Fisher-Ford Method, Jolly's Stochastic Method and Manly-Parr Method) have proved useful in the study of many populations from fruit flies, mosquitoes and grasshoppers to brown rats and salmonids. In the past, these capture-recapture methods have been a favourite hunting ground for statisticians who have delighted in the underlying theory. Begon is a biologist and has written for biologists, hoping to show "the essential simplicity of the mathematical techniques" and their potential as a biological weapon. In this he succeeds by virtue of a succinct prose, a clear lay-out and the good use of worked examples.

Capture-recapture methods are, however, only one of many techniques for estimating population size. This is very clear from T. R. E. Southwood's book, *Ecological Methods* (Chapman and Hall: London, second edition; hardback £10, paperback £3.75; for review, see *Nature* 278, 673; 1979), where over 50 pages are devoted to mark-release-recapture, but also nearly 100 pages to other methods for estimating absolute population size and a further 50 or so to techniques for relative population estimates. With Begon's aim of putting the biologist and his problems foremost, I would have liked to see, if only in passing, the subject viewed in its wider context.

Nevertheless, this book will be valuable for students who have to learn capture-recapture methods, for their teachers or for anyone contemplating their use in a research project.

## One-dimensional conductors

*Highly Conducting One-Dimensional Solids.* Edited by J. T. Devreese, R. P. Evrard and V. E. Van Doren. (Plenum: New York and London, 1979.) £26.77.

'ONE-DIMENSIONAL CONDUCTORS' are very popular at present because of the great diversity of physical phenomena which they exhibit. There are, of course, no truly one-dimensional conductors, and what we are dealing with are highly anisotropic solids composed on linear or chain-like structures. The systems which are discussed in some detail in this book are KCP or  $K_2Pt(CN)_4 \cdot Br_{0.3} \cdot xH_2O$ , and the organic charge transfer system TTF-TCNQ and its derivatives. In these solids the electronic anisotropy is the result of the directional nature of the orbitals involved in the formation of the conduction band. Mechanically, these two systems are almost isotropic. Other very anisotropic systems would include the  $(SN)_x$  polymer,  $NbSe_3$ , and polyacetylene-halogen complexes.

One of the main interests in the study of these systems is the search for high electrical conductivity or high temperature superconductivity. A theoretical paper by Little in 1964, in which an electron-exciton interaction was proposed as a likely mechanism for high temperature superconductivity has been an underlying influence in this work. Following this, initial reports by the Pennsylvania group in 1973 on the high conductivity of TTF-TCNQ below room temperature, sparked off the present spate of activity. Since then, the observation of incommensurate superstructures, which have been interpreted as Peierls distortions, forms an important aspect of this work. The degree to which one dimensional fluctuations depress the Peierls transition to zero temperature, and the competition between electron-electron coulomb repulsion and electron-phonon coupling on the Peierls transition, provide some of the main interests which are discussed in great detail in this book.

This is the most coherent treatment which has so far been given on the subject. The book consists of eight chapters written by well known experts deeply involved in the subject. The chapters are by Berlinsky, Comes and Shirane, Heeger, Schultz and Craven, Sham, Emery, Gutfreund and Little, and Bardeen.

It is, of course, impossible to cover even the main points in a short review. The book leans heavily on the more physical aspects, and even here perhaps on the more theoretical problems. This

Top left, Madonna Lily, etching by Nicolas Robert, from his *Diverses Fleurs* (1675); top right, White Lily, aquatint by J. C. Stadler, in R. J. Thornton's *Temple of Flora* (1799-1807); bottom, Crocuses, line engraving by Crispin de Passe, from his *Hortus Floridus* (1614).

A new exhibition, entitled *Flowers in Art from East and West*, opened at the British Museum on 10 May and will continue until 9 September, 1979. The exhibition brings together a wide range of floral art, including the work of many of the greatest painters and draughtsmen working in many parts of Europe and Asia from the ninth century AD to the present day. The various techniques of European print-

making and the woodblock printing of the Far East are also illustrated. A book of the same title, from which the above illustrations are taken, is being published simultaneously by the British Museum Publications Department. Paul Hulton, Deputy Keeper of Prints and Drawings, and Lawrence Smith, Keeper of Oriental Antiquities, provide not an accompanying catalogue to the exhibition but a proper book which can be read on its own and which covers the development of floral art, starting with the early manuscripts of the Byzantine Empire. The book is beautifully produced, with both colour and black and white illustrations, in hardback (£7.95) and paperback (£3.95).

should not frighten off those interested in the more experimental or chemical side of this topic, as there is a good deal to learn from the contents. It is certainly the best treatment of the subject of one-dimensional systems that

I have seen, and it can be warmly recommended.

A. D. Yoffe

A. D. Yoffe is Reader in Physics at the Cavendish Laboratory, University of Cambridge, UK.

# obituary

## Leland J. Haworth

DR LELAND J. HAWORTH, prominent physicist, administrator and government official, died on 5 March 1979, in Port Jefferson, New York, at the age of 74. A former director of the Brookhaven National Laboratory, commissioner of the United States Atomic Energy Commission, and director of the United States National Science Foundation, he brought to those organisations a wealth of experience as a teacher, a research scientist, a project leader and a science administrator.

His activities were not restricted to science development in the U.S. only. A strong advocate of international co-operation in science, he played an active role in fostering such co-operation.

Leland Haworth first became involved with 'big science' when he was engaged in major microwave radar research and development programmes at the Massachusetts Institute of Technology's Radiation Laboratory from 1941 to 1946. His responsibilities grew from those of a components development engineer to those of head of the Receiver Components Division and a member of the laboratory's steering committee. His specialty was electronics, especially in data presentation and precision instrumentation.

Following a brief return to the University of Illinois as professor of physics, Haworth in 1947 joined the Brookhaven National Laboratory (BNL) as assistant director in charge of special projects. Brookhaven was established in 1946 by the United States Government and Associated Universities, Inc. (AUI) as a multidisciplinary research institution, a primary purpose of which was to provide special facilities essential for basic research in nuclear and related sciences.

Haworth was appointed director of Brookhaven in 1948. He stimulated the development of a truly user-oriented philosophy of service to the scientific community, including the development and provision of ever more advanced facilities. In the early 1950s the Cosmotron (a 3.0 GeV proton accelerator) and the graphite research reactor were brought into service. The 30 GeV alternating gradient synchrotron (AGS) was authorised in 1954, brought into operation in 1960, and today remains one of the key elements in the United States high energy physics programme. Similarly, under his

Brookhaven National Laboratory

direction, construction of the high flux beam reactor (40 MW) was initiated in 1959, and today it is still the major U.S. research reactor providing external high intensity beams of neutrons for research in physics, chemistry and biology.

Haworth's position as director of Brookhaven and his personal interest in high energy accelerator development were of great benefit to CERN both in the initial planning and development of that institution and in bringing the alternating gradient focusing concept, through CERN and BNL joint studies, to a reality in the Brookhaven AGS and the CERN proton synchrotron. This close cooperation between the two institutions has continued.

From 1951 to 1960, Haworth also served as vice president of Associated Universities, Inc. He was named president in 1960 and held that post, while continuing as laboratory director, until the spring of 1961.

Leland Haworth immersed himself completely in every activity he undertook. His drive, his insistence on facts and accuracy, his pursuit of excellence and his clarity of expression were hallmarks. If Haworth did it, it was done well. It might have taken longer but it was done correctly. His leadership and, above all, his consideration for staff and regard for their capabilities and achievements earned the respect and admiration of all of his associates.

Haworth's influence extended beyond Brookhaven: his services were in

demand as a member of numerous study groups and advisory panels—for the White House, the Department of Defense and other U.S. Government Agencies.

In 1961, President John F. Kennedy appointed Haworth commissioner of the U.S. Atomic Energy Commission. He rapidly became involved in matters of national security, civilian energy development and the support of fundamental research. As a commissioner, he was heavily involved in the nuclear weapons development programme and in the preparation of the 1962 AEC Report to the President on civilian nuclear power.

Haworth recognised the urgent need for restraint in nuclear weapons development, especially in the test programmes then carried out primarily in the atmosphere. He advocated a test ban that could be readily monitored by national means, an approach that led to the limited test ban treaty prohibiting testing in the atmosphere and under water.

The Atomic Energy Commission's 1962 Report to the President on civilian nuclear power was a masterpiece of its time. It was a major governmental energy planning document and, though its thrust was nuclear, reference was made to the need for conservation and to the development of coal resources. Haworth's analytical approach, rigorous logical presentations and other contributions to the study gave it substance and credibility and set the tone for what is now a necessary ingredient of all energy planning.

President Kennedy asked Haworth to leave the Atomic Energy Commission in order to become director of the National Science Foundation; he assumed office on 1 July, 1963. During Haworth's six-year term, he brought the foundation to maturity in a period that saw great expansion of federal support for the conduct of basic science. He guided the development of a programme which increased the number of high-quality institutions across the nation, and he pioneered NSF efforts to link fundamental science to applied science and technology.

Haworth returned to AUI in 1969 as special assistant to the president. He continued as a consultant to the president and to the BNL director following his retirement in 1977.

Leland John Haworth was born in Michigan on 11 July 1904. He grew

up in Indiana and attended Indiana University, receiving his AB in 1925 and AM in 1926, both in physics. In addition to his academic pursuits, he participated in varsity baseball and tennis. He received his PhD in physics from the University of Wisconsin in 1931.

He was an instructor in physics at the University of Wisconsin from 1930 to 1937. During his graduate work and until 1934, he did research in solid state physics, specialising in the surface structure of metals. In 1934 he switched to nuclear physics, which thereafter remained his principal field.

Following one year as a Lalor Fellow in physical chemistry at the Massachusetts Institute of Technology, Haworth, in 1938, joined the physics department of the University of Illinois. His association with Illinois continued until 1947 except for five years of war-time leave at MIT.

Dr Haworth was a member of the board of directors of Oak Ridge Associated Universities (ORAU) from 1959 to 1961, and again from 1971 to February 1978, when he was elected director emeritus—the first time ORAU had made such an appointment.

He was a member of the National Academy of Sciences, the American Philosophical Society, Phi Beta Kappa and Sigma Xi. He was a fellow of the American Physical Society, the New York Academy of Sciences, the American Academy of Arts and Sciences, and the American Nuclear Society (member of board of directors, 1955–60; president, 1957–58).

For his work during World War II, Haworth received the President's Certificate of Merit. A mesa in the Antarctic and an asteroid have been named in his honour. He was the recipient of many honorary degrees.

The name of Haworth is synonymous with meticulous care for the work at hand. His traits of objectivity, attention to detail and sensitivity to the problems of others influenced all who worked with him, and we are the better for it. The institutions with which he worked have been left with a Haworth heritage, and they are the better for it.

## W. R. Aykroyd

DR WALLACE RUDELL AYKROYD, CBE, who died on 7 February 1979, aged 79, was a nutritionist of international renown since the early days of his career. His ability for meticulous work and great clarity of thought were soon recognised and his powers of organisation and administration left their mark in the many posts of distinction he held, particularly as the first Director of the Nutrition Division of the Food and Agriculture Organisation of the United

Nations from 1946 until 1960. His capacity to marshal facts and produce scientific reports in stylish and fluent prose made his publications important and influential in the fields of nutrition, public health and agriculture.

Graduating in medicine at Trinity College, Dublin, in 1924, where he was awarded the Vice-Chancellor's prize in English prose, he was appointed House Surgeon at the General Hospital, St John's, Newfoundland. He became interested in the deficiency diseases of the poorer fishermen and published an article on vitamin A deficiency in 1928 and a comprehensive report, 'Beriberi and other Deficiency Diseases in Newfoundland and Labrador', in the *Journal of Hygiene* in 1930. This 30-page report illustrates well the qualities which were to become the hallmark of his work—a broad approach, clear presentation of facts and a deep compassion for the unfortunate victims of malnutrition. He recognised that the diseases found were not due to deficiencies of single nutrients but multiple deficiencies due to poverty and a monotonous winter diet. His findings were used, and confirmed, by a team, which included B. S. Platt and W. H. Sebrell, conducting a medical survey of nutrition in Newfoundland some fifteen years later.

After his appointment to the Health Organisation of the League of Nations in 1931 he pursued his research into the link between malnutrition and poverty at a time of international recession and severe unemployment. His report, *Diet in Relation to Small Incomes*, published by the League of Nations in 1933, included a scholarly discussion on adequate dietary standards and satisfactory nutrition at low cost and his critical appraisal and distrust for the high protein allowances recommended was well in advance of his time and makes salutary reading today. The report is a valuable historical record of the time, containing studies of working class diet and expenditure on food in Germany, England and the USA.

The Health Organisation of the League of Nations decided, in 1934, that a general report on nutrition was needed after some ten years of studies of nutrition in the field of public health. Dr Aykroyd and Dr Etienne Burnet were asked to undertake this by making a series of enquiries in different countries and to report on nutritional status, research and policies. Their publication, *Nutrition and Public Health*, printed by the League of Nations in 1935, was an important statement of the current nutrition situation and was used extensively by international committees in public health and agriculture as well as the International Labour Office. Following this report the Health Organisation

set up a Technical Commission for the Study of Nutrition which convened meetings of groups of experts who then produced reports (a procedure continued by FAO and WHO). The first report, *The Physiological Bases of Nutrition* (1936), relied heavily on the findings of the Aykroyd and Burnet report.

Following his appointment as Director of the Nutrition Research Laboratories in Coonoor, India, in 1935, Dr Aykroyd continued his work as an expert for the Technical Commission including research on the effect on nutrients of the milling of cereals and the influence of climate on food requirements. His work in India greatly enhanced the reputation of nutrition research in that country and the world famous Indian National Institute of Nutrition at Hyderabad was the result of his efforts. To this day, revised editions of *The Nutritive Value of Indian Foods and the Planning of Satisfactory Diets* retains his name as principal author in recognition of his original concepts for the work.

During his period at FAO from 1946 Dr Aykroyd's leadership gave the Nutrition Division a fine start and the reports of the Expert Committees (some jointly with WHO), which owed a lot to his guidance and editing, are consulted throughout the world. After his retirement from FAO, in 1960, he joined Professor B. S. Platt at the Department of Human Nutrition, London School of Hygiene and Tropical Medicine, where, as Senior Lecturer, he helped to set up regular courses which led to the present MSc in Human Nutrition, attended by graduates from all over the world. He wrote several books at this time including *Food for Man and The Conquest of Deficiency Diseases* which explained nutritional problems in terms understandable and interesting for the untrained reader. During his work as co-author of the FAO Studies, *Legumes in Human Nutrition and Wheat in Human Nutrition* he was able to indulge in his love of history as well as use his powers of marshalling a mass of facts into lucid and readable prose.

This interest in history, which had led to the writing in 1935 of *Three Philosophers*, one of whom had been his great hero, Lavoisier, was also evident in his book *Sweet Malefactor: Sugar, Slavery and Society*.

During his active retirement he carried on with nutrition consultancy work for WHO and OXFAM and found time to write *The Conquest of Famine*. A fitting tribute was made when this received the first award of a joint book award scheme of the British, Swedish and American Nutrition Foundations.

## HEPARIN-ULTROGEL® A4R

Affinity chromatography  
adsorbent for :

- coagulation factors
- lipoproteins
- lipoprotein lipases
- protein synthesis factors
- DNA and RNA polymerases

Main characteristics :

- Immobilized heparin per ml  
of gel : 4 - 6 mg
- Adsorption capacity :
  - bovine AT III : 1.3- 2.3 mg/ml
  - protamine sulfate : 7 - 10 mg/ml
  - toluidine blue : 2 - 3 mg/ml
- Temperature stability : 2 to 120° C.

Technical brochure available upon request:

Amersham

Circle No. 07 on Reader Enquiry Card.

## <sup>14</sup>C-Protein molecular weight markers

Labelled proteins of known molecular weight for use as markers in gel electrophoresis are available from TRC NOW

### [<sup>14</sup>C]Methylated

Lysozyme	CFA.605	MW 14,300
Carbonic anhydrase	CFA.622	MW 30,000
Ovalbumin	CFA.623	MW 46,000
Bovine serum albumin	CFA.621	MW 69,000
Phosphorylase b	CFA.609	MW 92,500
Myosin	CFA.625	MW 200,000

Specific activity 3–30μCi/mg of protein

### Also available

[<sup>14</sup>C]Methylated protein mixture CFA.626  
Contains equal activities of each of the 6 markers

Please enquire for further details

# announcements

## Appointments

The National Academy of Sciences has elected 15 distinguished scientists from seven countries as foreign associates of the Academy: **Neil Bartlett** (UK), professor of chemistry, University of California, Berkeley, California; **Donald O. Hebb**, chancellor (retired), McGill University, Montreal, Canada; **John R. Hicks**, professor emeritus, University of Oxford, All Souls College, Oxford, UK; **Sir Andrew F. Huxley**, Foulerton research professor of the Royal Society, University College, London, UK; **Pierre Joliot**, chef de service, Institut de Biologie Physico-Chimique, Paris, France; **Michael S. Longuet-Higgins**, Royal Society research professor, department of applied mathematics and theoretical physics, University of Cambridge, UK; **Mary Lyon**, head, genetics section, Medical Research Council Radiobiology Unit, Berkshire, UK; **Digby Johns McLaren**, director general, Geological Survey of Canada, Ontario, Canada; **Sir Gustav J. V. Nossal**, director, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia; **Alan Robertson**, deputy chief scientific officer, Agricultural Research Council, Animal Breeding and Genetics Research Organisation, Edinburgh, UK; **Abdus Salam**, professor of physics, Imperial College, London, UK; **Jean-Pierre Serre**, chair of algebra and geometry, College de France, Paris, France; **Roger Y. Stanier**, professor, department of biochemistry and microbial genetics, Institut Pasteur de Paris, Paris, France; **Cornelius A. G. Wiersma** (Netherlands), professor of biology, California Institute of Technology, Pasadena, California; **Yakov B. Zeldovich**, academician, Institute of Applied Mathematics, Academy of Sciences, Moscow, USSR.

The Royal Society has elected the following as Foreign Members of the Society: **Dr Julius Axelrod**, Chief of the Section of Pharmacology at the National Institute of Mental Health, Bethesda; **Professor Joshua Lederberg**, President of the Rockefeller University, New York; **Professor Jerzy Neyman**, Professor and Director of the Statistical Laboratory at the University of California, Berkeley; **Professor Yakov Borisovich Zeldovich**, Professor at the Institute of Chemical Physics in the Academy of Sciences, Moscow, USSR.

The Council of the Royal Society has appointed **Professor R. K. O'Nions** to a Royal Society Research Professorship under the scheme established in 1962 with support from HM Government for the Royal Society Research Professorships in universities in the UK.

**Dr Austin Woodland**, CBE, the present Director of the Institute of Geological Sciences, is to retire at the end of May this year and the Natural Environment Research Council has appointed **Professor G. M. Brown**, at present Professor of Geology at the University of Durham, to succeed him.

**Dr Patrick Grove**, Group Managing Director of the Radiochemical Centre is retiring on 16 May 1979. He will be succeeded by **Dr J. Stuart Burgess** who has been made a director of the company from 3 May 1979.

**Sir Charles Pereira**, formerly chief scientist, Ministry of Agriculture, Fisheries and Food, has been appointed Royal Society Inter-University Council Visiting Professor at the University of Nairobi, under a scheme to help scientific interchange between the UK and the Commonwealth.

**J. G. Dawson**, Chairman and Managing Director of the Zenith Carburettor Company Limited, has been elected the new President of the 72,000-member Institution of Mechanical Engineers.

The Agricultural Research Council has approved the appointment of **Professor John Postgate** as Director of the Unit of Nitrogen Fixation, University of Sussex, when the present Director, Professor Joseph Chatt, retires in March 1980.

The Governing Body has appointed **Dr Peter R. Day** to become Director of the Plant Breeding Institute from 2 July 1979.

**Dr John P. Hearn** has been appointed Director of the Wellcome Laboratories of Comparative Physiology, Institute of Zoology, The Zoological Society of London and will take up his appointment on 1 September 1979.

**Dr R. W. Nesbitt**, Reader in Geology at Adelaide University, has been appointed to a Chair of Geology with effect from 1 September 1979.

**Dr David J. Sherratt** has been appointed to the Chair of Genetics in the University of Glasgow with effect from 1 April 1980.

**Mr Christopher Ian Pogson**, at present Lecturer in Biochemistry in the University of Kent at Canterbury, has been elected to a Chair of Biochemistry at the University of Manchester.

**Dr Robert M. Farr**, Lecturer in Social Psychology at University College London, has been appointed to the newly established second Chair in Psychology in the University of Glasgow from 1 October 1979.

The British Committee of Award announces the following appointments to Harkness Fellowships of the Commonwealth Fund: **P. H. Allen** (Freshfields, and Exeter College, Oxford) Business Administration; **C. R. Bean** (H.M. Treasury) Economics; **Miss A. Campbell** (Department of Psychology, University of Oxford) Psychology; **H. J. Davies** (H.M. Treasury) Management Studies; **Miss J. Dodd** (King's College, Cambridge) Neurobiology; **Miss R. Elias** (BBC Television) Journalism; **P. J. Fray** (Clare College, Cambridge) Physiological Psychology; **L. N. Goldman** (Jesus College, Cambridge) American History; **D. M. Herman** (Trinity College, Cambridge) Literature; **H. D. Keelan** (Queen's College, Cambridge) Music; **Miss S. Laird** (St Anne's College, Oxford) Soviet Studies; **S. F. Lee** (Balliol College, Oxford) Law; **G. A. M. Leggatt** (King's College, Cambridge) Philosophy of Law; **Miss P. Lund** (Department of Physiology, University of Newcastle upon Tyne) Endocrinology; **J. N. Pearson** (Department of the Environment) Public Administration; **R. J. Peel** (Arthur Andersen & Co.) Business Administration; **E. Powell** (Pembroke College, Oxford) Legal History; **M. F. Scanlon** (Royal Victoria Infirmary, Newcastle upon Tyne) Endocrinology; **P. A. Swaab** (Christ's College, Cambridge) American Literature; **J. Watkins** (Hammersmith Hospital, Royal Postgraduate Medical School) Medicine.

## Awards

**Finlay MacRae**, District Officer with the Forestry Commission, has won an international conservation award for his work in conserving the native Caledonian Pinewoods of Glen Affric. The award is made by the Society of American Travel Writers.

**Dr Greg Clark**, a Principal Research Scientist with the Division of Mineral Physics in Sydney, has been awarded the Pawsey Medal for distinguished research in experimental physics.

The André Lichtwitz prize (10,000 French Francs) is awarded every year by INSERM ("Institut National de la Santé et de la Recherche Médicale") for distinguished clinical or fundamental research on calcium and phosphorus metabolism carried out by a French or foreign scientist (or a team). Applicants who have previously applied are allowed to apply again. Applications: Director of the INSERM (c/o Mlle C. Chirol, 101 rue de Tolbiac, 75645-PARIS CEDEX 13, France) by 30 June 1979.

The Clarke Institute of Psychiatry, Annual Research Fund Award is awarded annually to a clinical or basic scientist who has published a report or dissertation on outstanding research within the field of mental health conducted during the preceding year. The scientists must have carried out his work in Canada while resident in Canada. He may apply or be nominated for the prize up to 1 June in the year following publication. Applications: J. E. Stewardson, Secretary, Research Fund Committee, Clarke Institute of Psychiatry, 250 College Street, Toronto, Ontario Canada M5T 1R8.

## Meetings

7 June, **Conference on Forestry Policy**, London (The Royal Society of Arts, 8 John Adam St, Adelphi, London WC2).  
12-14 June, **Fuel Economy and Emissions of Lean Burn Engines**, London (The Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1, UK).  
12-13 June, **Rural-Urban Interchange for Progress**, London (The Overseas Development Ministry, Eland House, Stag Place, London SW1, UK).  
18-20 June, **Engineering Aspects of Magnetohydrodynamics**, Butte (D. R. Brown, 18th MHD Symposium, Merdi, PO Box 3809, Butte, Montana 59701).  
20 June, **Experience of Cathodic Protection in Steam and Process Plant**, London (The Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1, UK).  
29 June, **Inflammation Mechanisms, Therapy and Investigative Techniques**, Glasgow (Dr I. J. Zeitlin, Dept of Physiology and Pharmacology, University of Strathclyde, George St, Glasgow, UK).  
5-7 July, **Scientific Criteria and Methods for Drug Assessment**, Rome (Fondazione Giovanni Lorenzini, Via Monte Napoleone, 23, 20121, Milan, Italy).

9-13 July, **The Mechanisms of Reactions in Solutions**, Canterbury (Dr J. F. Gibson, The Chemical Society, Burlington House, London W1, UK).  
10-11 July, **Noise and Vibration of Engines and Transmissions**, London (Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1, UK).  
12-13 July, **Dietary Management of Disease**, London (Dr M. R. Turner, British Nutrition Foundation, 15 Belgrave Square, London SW1, UK).  
15-17 August, **20th Canadian High Polymer Forum**, Quebec (Dr Ian McEwan, CIL Paint Research Laboratory, 1330 Castlefield Ave, Toronto, Ontario, Canada M6B 4B3).  
29-31 August, **4th International Symposium on Mycotoxins and Phycotoxins**, Lausanne (Prof. Palle Krogh, Dept of Veterinary Microbiology, Purdue University, West Lafayette, Indiana 47907).  
12-14 September, **Charged-Coupled Devices**, Edinburgh (Mr W. Campbell, Centre for Industrial Consultancy and Liaison, University of Edinburgh, 16 George Square, Edinburgh, UK).  
16-21 September, **Advanced Immunoassay Workshop**, Guildford (Mr B. A. Morris, Division of Clinical Biochemistry, Dept of Biochemistry, University of Surrey, Guildford, Surrey, UK).  
18-21 September, **The Economics of Information**, Brighton (Aslib, 3 Belgrave Square, London SW1, UK).  
26-28 September, **New Coal Upgrading Processes**, Luxembourg (Commission of the European Communities, Bureau d'Organisation et de Coordination des Conférences, Bâtiment Jean Monnet, B1/32, Plateau du Kirchberg, Luxembourg).  
28 September, **Practical Applications of Microwave Energy**, Manhattan (Dr D. Y. C. Fung, Call Hall, KSU, Manhattan Kansas 66506).  
1-3 October, **10th Annual Underwater Mining Institute**, Galveston (Prof. J. Robert Moore, Marine Science Institute, The University of Texas, PO Box 7999, Austin, Texas 78712).  
1-3 October, **Gesellschaft für Immunologie**, Innsbruck (Prof. Dr G. Wick, Institute for General and Experimental Pathology, Fritz-Pregl-str. 3, 6020 Innsbruck, Austria).  
1-3 October, **2nd International Recycling Congress**, Berlin (CRE/MER, PO Box 33002 10, D-1000 Berlin 33, FRG).  
2-4 October, **Grain Dust—Its Characteristics, Explosibility, Hazard Control and Utilization**, Manhattan (Dr B. S. Miller, US Grain Marketing Research Laboratory, 1515 College Ave, Manhattan, Kansas 66502).  
3-6 October, **1st International Congress on Hormones and Cancer**, Rome (S. Lacobelli, Laboratorio di Endocrinologia Molecolare, Istituto di Clinica

Osterrica e Ginecologica, Università Cattolica del S. Cuore, Via della Pineta Sacchetti, 644, 00168, Rome, Italy).  
3-6 October, **Hormones and Cell Regulation**, Strasbourg (Dr J. Nunez, Unite de Recherche sur la Glande Thyroïde, Inserm, 79 Ave du General Leclerc, 94 Bicetre, France).  
9 October, **Testing the Body**, London (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).  
4-18 October, **Latent and Persistent Virus Infections in Man**, Israel (KENES, 8 Shmuel Hanagid St, PO Box 983, Jerusalem, Israel).  
9-11 October, **Progress and Problems in Radioelement Analysis**, Gatlinburg (Public Relations Dept, Union Carbide, Nuclear Division, PO Box Y, Oak Ridge, Tennessee 37830).  
15-18 October, **Weather and Air Pollution**, Scarborough (National Society for Clean Air, 136 North St, Brighton).  
16-17 October, **Quantitative Surface Analysis**, Teddington (Dr C. Lea, Division of Chemical Standards, National Physical Laboratory, Teddington, Middlesex, UK).  
22-25 October, **RECLAN 79**, Eastbourne (The Conference Secretariat, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).  
28-31 October, **10th Yugoslav Symposium on Biophysics**, Radenci (Gregor Cevc, J. Stefan Institute, Jamova 39, PO Box 199, 61001 Ljubljana, Yugoslavia).  
28 October-2 November, **Water Chlorination: Environmental Impact and Health Effects**, Colorado (Public Relations Dept, Union Carbide Nuclear Division, PO Box Y, Oak Ridge, Tennessee 37830).  
29 October-3 November, **12th Annual Meeting of the American Association of Stratigraphic Palynologists**, Dallas (H. M. Simpson, Geoscience Research, ARCO Oil and Gas Company, PO Box 2819 (EXP-1060, Dallas, Texas 75221).  
2-4 November, **Machining**, Bournemouth (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).  
13 November, **Significance of Defects in the Failure of Fibre Composites**, London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).  
13-15 November, **Post-Harvest Crop Conservation**, Harrogate (Dr R. Gordon, 19 Homewood Road, St Albans, Herts, UK).  
27-30 November, **Forage Conservation in the '80s**, Brighton (The Conference Secretariat, British Grassland Society, The Grassland Research Institute, Hurley, Maidenhead, Berks, UK).  
26-29 November, **4th World Ozone Congress**, Houston (R. S. Croy, International Ozone Association, 14805 Detroit Ave, Cleveland, Ohio 44107).

# newly on the market

**Agarose gel.** LKB introduce the LKB Agarose-EF—a new type of agarose with very low electroendosmosis, and the new 1802 Ampholine carrier ampholytes for electrofocusing in agarose. These open a wide range of new application areas for electrofocusing.  
**Circle No. 43 on Reader Enquiry Card.**

**Camera back.** Bausch and Lomb have announced a new 35-mm camera back for Series II photomicrographic equipment and the AX-1 automatic exposure controller. The camera back fits all current focusing tubes and includes 3× and 5× adaptors. An automatic dark slide is incorporated which opens when the camera back is snapped into the adaptor on the focusing tube, and closes automatically when the back is removed. An opening in the camera back accepts a plastic strip on which pertinent data can be recorded. The data are then photographed along with the slide to simplify photographic identification. The camera back is par-focussed and par-centred with the microscope eyepieces.  
**Circle No. 44 on Reader Enquiry Card.**

Bausch and Lomb camera back

**Portable container.** Laboratory Impex. Magic-Temp is a fully portable container designed to transport samples or other material safely and at the correct temperature. The unit will work on normal mains electricity or from the cigarette lighter socket of a car or van. Magic-Temp operates in 3 modes: as a refrigerator, a freezer and an incubator. It has a deep drawn heavy duty aluminium inner chamber, foam-in-place polyurethane insulation and an exterior of high impact plastic. The capacity of Magic-Temp is more than 14 l, total weight 13 kg.  
**Circle No. 45 on Reader Enquiry Card.**

**Calibration aid** for microscopists. Dunn and Reidman. The Photomicrograph Scale Marker from Dunn and Reidman is designed on a slide-rule principle, and is used for the direct application of any desired size of scale mark onto photomicrographs. The user simply selects a scale mark and pulls out the inner slide to correspond with the photograph magnification, thus automatically setting the instrument to produce the selected scale mark. Another function of this instrument is that of measuring the real-life size of structures directly from photomicrographs. The Photomicrograph scale marker is constructed from high-quality plastic and is supplied in a protective pouch.  
**Circle No. 46 on Reader Enquiry Card.**

**Diffusion zone reader.** Dynatech. The improved diffusion zone reader from Dynatech will accept bioassay plates up to 25 cm<sup>2</sup> (twice the size of earlier models). Designed for the measurement of precipitin rings and antibiotic sensitivity zones, the machine can also be used in electrophoretic and immunodiffusion studies. A clear direct optical image of the zone to be measured is provided. The object is lit by dark ground illumination and the measuring cursor lines are projected by a top-illumination system so that they are superimposed onto the zone. Simple adjustments can be made to the optical system to compensate for parallax shift and to allow for variations in the heights of different objects.  
**Circle No. 47 on Reader Enquiry Card.**

**Laboratory freeze drier.** ChemLab. The model SB3 is a compact freeze drier which incorporates a built-in refrigeration system. The SB3 is normally fitted with a manifold to which laboratory glassware can be attached. The condenser chamber has an ice capacity of 3 l. The coil is chilled by the circulation of Freon 502 from the refrigeration unit. This model is normally supplied complete with a manifold and the flange of the manifold is connected to the side of the condenser. The vacuum pump for use with the model SB3 should have a displacement of about 50 l min<sup>-1</sup>.  
**Circle No. 48 on Reader Enquiry Card.**

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

**Digital thermometers.** Digical announce a range of portable digital thermometers for medical and scientific use. These thermometers have the advantage of permanently pre-set calibration, interchangeability of all probes, and fast response (<15 s in certain circumstances). A range of 25 probes is available. Options available include: model DC-1 thermometer—range -50 °C to +150 °C (resolution 0.1 °C); model DC-M thermometer—range +30.00 °C to +49.99 °C (resolution 0.01 °C). Multi-input unit for differential application; alarm units; readout option in °F are available additional features.  
**Circle No. 49 on Reader Enquiry Card.**

Digital portable thermometer

**Carcinoembryonic antigen control serum.** Bio-Rad. Carcinoembryonic antigen (CEA) control serum (human) is now available from Bio-Rad Laboratories. This material is manufactured from pooled human serum and offers the user two levels of the antigen. Level 1 provides CEA representative of the high normal range (2.5–5.0 ng ml<sup>-1</sup>) while level 2 represents the range clinically significant for malignancies (10–20 ng ml<sup>-1</sup>). CEA control serum is a stable, lyophilised control serum and contains no preservatives, stabilisers or other catalytic or non-reactive ingredients.  
**Circle No. 50 on Reader Enquiry Card.**

**High performance GC/MS system.** Varian. The new MAT 212 is a high performance GC/MS system. Its resolution is >20,000 (10% valley), the accuracy of mass determination better than 3 p.p.m. The basic system includes a dual-column Varian 3700 gas chromatograph. The link between Varian 3700 and mass spectrometer is an open split coupling for capillary and packed columns. A single stage all-glass jet separator for packed column work is optional.  
**Circle No. 51 on Reader Enquiry Card.**

**Automatic sputter coater** for scanning electron microscopy. Nanotech. Advantages of the Semprep 2 sputter coater from Nanotech for routine EM preparation include a degree of automation built into the standard equipment that ensures reproducible results without the need to set up controls for each deposition, and cleanliness guaranteed by the integral two-stage rotary vacuum pump and associated metal pipework. A built in electron deflection system and associated specimen cooling prevent thermal damage to sensitive specimens, and a closed loop system controls the sputtering current and voltage. The sputtering current required is selected and held constant electronically. The sputtering voltage is selected and is then held constant by closed loop control of the argon gas inlet valve.

**Circle No. 52 on Reader Enquiry Card.**

The Nanotech Semprep 2 sputter coater

**IR Spectrophotometers.** Perkin-Elmer. The microprocessor controlled Model 98 series consists of three instruments: the Model 598, scanning from 4,000  $\text{cm}^{-1}$  to 200  $\text{cm}^{-1}$ , the Model 398, scanning from 4,000  $\text{cm}^{-1}$  to 400  $\text{cm}^{-1}$ , and the Model 298, from 4,000  $\text{cm}^{-1}$  to 600  $\text{cm}^{-1}$ . There is a choice of three slit programs and six scan times. A five-digit wavenumber display allows the monochromator to be set accurately and reproducibly to any chosen frequency. The chart and monochromator drives are synchronised by the microprocessor. Other standard features include repeat scan facilities, wavenumber limits, choice of chart formats and rapid indexing of both chart and monochromator to 4,000  $\text{cm}^{-1}$ .

**Circle No. 53 on Reader Enquiry Card.**

**Monoclonal anti-Thy 1.2.** New England Nuclear (NEN) has announced the availability of a sensitive tool in cellular research, monoclonal anti-Thy 1.2, for identification, localisation and selective isolation of mouse T-cell lymphocytes. This high-titre anti- $\theta$  antibody is extraordinarily specific for the Thy 1.2 antigen on the surface of mouse T-cell lymphocytes. It is offered in two concentrations: as  $\sim 1$  mg immunoglobulin, or  $\sim 0.1$  mg immunoglobulin, both supplied in 1 ml of buffer system.

**Circle No. 54 on Reader Enquiry Card.**

**Balances.** Mettler. The PL/SE range of balances from Mettler has been designed specifically for hot cell use. Only the weighing cell is located in the radioactive or sterile environment—the electronics which convert the weight readings to a digital form are placed outside. The rugged construction of the three PL/SE balances makes them suitable for use in highly radioactive surroundings and the 5-m long connection obviates the need for a separate power supply in the weighing cell. The PL200SE, PL1200SE and PL3000SE offer a weighing range of 220–0.001 g, 1,200–0.01 g and 3,500–0.1 g, respectively.

**Circle No. 55 on Reader Enquiry Card.**

**pH Electrodes.** MSE. Four 'unbreakable' pH electrodes, a pH meter, and a new type of automatic temperature compensation probe have been introduced by MSE Scientific Instruments. The model 9115 semi-micro electrode for measurements in test tubes is 6 mm in diameter. The model 9125 is 1 ft long. The model 9105 is a standard combination pH electrode, while the model 9135 has a flat sensing tip for measurements of pH on surfaces. All electrodes are permanently gel-filled combination electrodes, with tough epoxy bodies and they can be supplied with a variety of plugs. Also new is the model 501 pH meter; pH to the nearest 0.01 units and automatic temperature compensation probe which enables the meter to be used also as a digital thermometer.

**Circle No. 56 on Reader Enquiry Card.**

**Dewar flasks.** Day-Impex have introduced two additions to their 'Dilvac' range of glass Dewar flasks in stainless steel containers. The first is a 7-l size, which has toggle-clamps to secure the lid, a strong carrying handle and a cushioned base. On this model there is also a handle on the lid, and the wide diameter base of the container creates a very low centre of gravity, ensuring safe transportation of specimens etc. The second new style is a range of wide-mouthed shallow form Dewars in four sizes. Borosilicate glass is used as an inner vessel for the robust stainless steel casing. The wide mouths are designed so that boiling flasks of four sizes, 100, 250, 500 and 1,000 ml, will fit easily.

**Circle No. 57 on Reader Enquiry Card.**

**Plasma chemistry equipment.** Nanotech have now developed their range of plasma chemistry equipment to allow fully automatic load tuning in conjunction with closed loop control of the RF power levels. Automatic controls allow unattended operation for long reaction periods and also operation by unskilled personnel. The applications of plasma chemistry in-

clude organic removal and sample preparation for atomic absorption spectroscopy.

**Circle No. 58 on Reader Enquiry Card.**

**Data analyser.** Du Pont. The MWD-1 from Du Pont is a compact data collection and analysis system for automatic acquisition, reduction, and printout of molecular weight distribution (MWD) data. This system eliminates the manual calculations usually associated with chromatographic polymer characterisation techniques. Total high performance size exclusion chromatography analyses in less than 10 min are routinely possible. The MWD-1 automatically adjusts raw chromatographic data for column dispersion and reports corrected molecular weight results. Another feature is on-line calibration with either narrow or broad base standards. Calibration routines can be entered into the system and stored in memory via magnetic programming strips.

**Circle No. 59 on Reader Enquiry Card.**

**Digester to determine trace elements.** Büchi. The Büchi digesting system digests organic and biological materials in a closed quartz apparatus. The main ranges of application lie in the analyses of foodstuffs and feedstuffs, clinical-medicinal chemistry and ecology. The system is automatic and can be operated by semi-skilled personnel. Digestion under total reflux in a closed system prevents foreign elements being carried in. The acid consumption is very low. The controls permit manual as well as automatic operation. The glass components of the six digestion points are interchangeable. The apparatus has 100-ml flasks as standard equipment. Six tests can be carried out simultaneously. Weighed samples of up to 30 g can be used. The digesting temperature is selectable between 150 and 360 °C.

## APPOINTMENTS VACANT

### UNIVERSITY OF KHARTOUM—SUDAN

Applications are invited for the post of  
**LECTURER**

**IN MEAT PRODUCTION**

in the

**DEPARTMENT OF  
ANIMAL PRODUCTION**

Salary scale (exclusive of cost of living allowance): £51,500 to £53,500 per annum (£51=£1.23 sterling). The British Government may supplement salary in range £3,894 to £4,542 per annum (sterling) for married appointee or £1,830 to £2,310 per annum (sterling) for single appointee (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; baggage allowance; superannuation scheme; unfurnished accommodation available; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct by air mail to Acting Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan, by July 18, 1979.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 1098(A)

### Re-advertisement UNIVERSITY COLLEGE OF NORTH WALES

Applications are invited for the post of  
**LECTURER**

**IN AGRICULTURE**

with particular responsibilities for Grassland Production. Applicants should have a degree in Agriculture, Agricultural Science, or a related discipline with a sound basis in Agronomy.

Applicants should be interested in developing research in the pasture-animal relationships with reference to the efficiency of utilisation of grassland, and in helping to co-ordinate the activities of a developing team interested in the wider field of Animal Production from Grassland.

The appointment, to commence on September 1, 1979, or any earlier date by agreement, will be to the Universities' Lecturer scale: £4,232 to £8,452 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: June 25, 1979. 2023(A)

### New Zealand UNIVERSITY OF CANTERBURY Christchurch SENIOR LECTURER/ LECTURER

**IN COMPUTER SCIENCE**

Applications are invited for the above-mentioned position. Applicants should have interests within the (very broad) areas of computer systems and languages, theory of computing, information systems, or other areas of non-numerical applications.

The salary for Lecturers is in a scale from NZ\$11,894 to NZ\$14,615 per annum. Promotion may be made on academic merit to Senior Lecturer where the salary range is from NZ\$14,983 to NZ\$17,145 (bar) NZ\$18,665 per annum.

Applications close on August 15, 1979.

Particulars, including information on travel allowances, study leave, housing and superannuation, may be obtained from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 1097(A)

### GEOCHRONOLOGIST

A Geochronology Laboratory is to be established at the University of Regina in the Department of Geology. The successful applicant will be required to design, set-up and operate a solid source mass spectrometry laboratory specialising in uranium-lead and zircon dating methods. The position will be of particular interest to persons with a strong physics background. A knowledge of solid state electronics, minicomputers and data handling. The position, which does not require any teaching or administrative duties, will commence as soon as a suitable candidate is found. Salary will be commensurate with qualifications and experience. Applications, which must indicate availability and salary expected, should be forwarded, along with three letters of reference, to Dr G. R. Parslow, Department of Geology, University of Regina, Regina, Saskatchewan, S4S 0A2, Canada (PRIOR TO JUNE 30, 1979). W121(A)

### NATIONAL VEGETABLE RESEARCH STATION ASSISTANT PLANT BREEDER

A SCIENTIFIC OFFICER is required to assist in research into onion and carrot breeding.

The appointment will be in the grade of Scientific Officer scale from £2,839 rising by annual increments to £4,415.

Minimum qualification required is a Degree in biological science or applied biology.

Non-contributory employers' additional pension scheme.

Full particulars and application form (to be returned by June 19, 1979) from the Secretary, National Vegetable Research Station, Wellesbourne, Warwick CV35 9EF. 1014(A)

### CHARING CROSS HOSPITAL MEDICAL SCHOOL (University of London) TWO RESEARCH ASSISTANTS

Applications are invited from graduates with First or Second class degrees in a biological science for the above posts, one tenable in the Department of Microbiology at Charing Cross Hospital Medical School and the other at the Institute of Obstetrics & Gynaecology at Queen Charlotte's Maternity Hospital, W.6. Work will be on vertical transmission of cytomegalovirus. Previous experience of virological techniques is not essential.

Salary £3,486 to £3,798 per annum plus £354 London Weighting Allowance (under review).

Further details obtainable from Dr. J. C. Coleman, 01-748 2040 extension 2499, and applications on forms from the School Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St. Dunstan's Road, London, W6 8RP. (2030)A

### UNIVERSITY OF RHODESIA DEPARTMENT OF GEOGRAPHY LECTURESHIP IN GEOGRAPHY

Applications are invited for the above-mentioned post. Candidate should indicate in their applications the full range of their interests and abilities as well as their special field of study. Preference may be given to persons whose special field of study is Geomorphology (with Biogeography).

**Salary Scales (Approx. Sg. Equiv.)** Lecturer Gr. I £7,021 by £264 to £8,077; Lecturer Gr. II £4,334 by £221 to £5,474 by £264 to £6,794. Both permanent, pensionable terms and short-term one or two-year contract are offered.

**Permanent, Pensionable Terms.** Family passages and allowance towards transport of effects on appointment. Installation loan of up to half of one year's salary if required. University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical leave and triennial contact visits with travel allowance. Superannuation and medical aid schemes.

**Short-term Contracts:** Family passages and allowance towards transport of effects. Assistance with accommodation for persons recruited from outside Rhodesia.

**Applications:** (6 copies) giving full personal particulars (including full names, place and date of birth, etc. qualifications, experience and publications, and names and addresses of three referees, should be submitted to the Registrar, University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia. Overseas applicants should send an additional copy of their applications to the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1 0PF. Further particulars may be obtained from either of the above.

Closing date for receipt of applications: June 30, 1979.

British subjects considering application for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 8727) or their nearest British Consular Office. 2026(A)

## Researcher

### Overseas Assignment

The Kuwait Institute for Scientific Research, a rapidly expanding institute for applied science and technology, is seeking a Researcher interested in a career challenge.

You should have a Ph.D. in Chemical Engineering or Civil Engineering with a minimum of 3 years' experience in Mix Design Core Analysis for road constructions.

Kuwait Institute offers attractive salaries commensurate with qualifications and experience, furnished housing, liberal fringe benefits including round trip air tickets and free medical benefits.

Please airmail your complete resume by July 25, 1979 to: Mr. Habib Al-Sahhaf, Personnel Manager, Kuwait Institute for Scientific Research, P.O. Box 24885, Safat, Kuwait, State of Kuwait. W144(A)

## Kuwait Institute for Scientific Research

**THE RESEARCH ORGANIZATION OF SYNTHELABO**  
an internationally recognized European Pharmaceutical Group located in Paris

*requires a*

## SENIOR PHARMACOLOGIST IN METABOLIC DISEASES

to lead the Group of Intermediary Metabolism in the Department of Biology

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

In order to succeed in this challenging and important post, the successful applicant, either male or female, must be capable of leading a team of graduates and technicians and would be responsible for both the fundamental and applied work of the group. The group is actively researching into anti-obesity and anti-hyperlipidaemic drugs and has an increasing interest in anti-diabetic drugs.

Applicants should be a PhD Biochemical Pharmacologist with at least five years post doctoral experience and preferably with industrial experience as well.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent directly to Mr. J. Brault at the following address:

**SYNTHELABO,  
58, Rue de la Glaciere,  
75013 Paris.**

**W154(A)**

**THE LONDON HOSPITAL  
MEDICAL COLLEGE  
(University of London)  
DEPARTMENT OF BIOCHEMISTRY  
JUNIOR LABORATORY  
SCIENTIFIC OFFICER/  
LABORATORY  
SCIENTIFIC OFFICER**

required for general duties which will include some research work.

Salary on Whitley Scale £2,259 to £3,344 per annum, including London weighting, according to age and experience. Four weeks annual holiday plus extra days when College is closed.

For further details from Dr C. W. Parr, Tel: 047 0644, ext. 20. Applications to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, quoting reference B/5/79. 1092(A)

**ROYAL POSTGRADUATE  
MEDICAL SCHOOL  
(University of London)  
DEPARTMENT OF  
CLINICAL PHARMACOLOGY  
SENIOR  
RESEARCH OFFICER  
(Postdoctoral)**

required for clinically orientated research on Prostacyclin. Applicants may be chemists, biochemists, or pharmacologists as both biological and GC-MS work is in progress. Prostaglandin experience is desirable but not essential.

The appointment is for up to two years. Salary £4,232 plus £502 London Allowance or £4,505 plus £502 London Allowance in first year.

Application forms and further particulars may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS, quoting ref. no. 20/202/N. 2001(A)

**FACULTY POSITION  
THE GRADUATE DEPARTMENT  
OF NUTRITION  
TUFTS UNIVERSITY**

has a faculty opening for a doctoral level person with teaching experience in animal as well as human nutrition, who will spend half time teaching students in the Department and in the School of Veterinary Medicine, and half time doing research.

Title, salary and types of research will be determined according to applicant qualifications.

Curriculum vitae and bibliography should be submitted to: Dr Stanley N. Gershoff, Chairman, Graduate Department of Nutrition; Director, Nutrition Institute, Tufts University, Medford, MA 02155.

Tufts University is an equal opportunity/affirmative action employer. W155(A)

**UNIVERSITY OF  
LONDON KING'S COLLEGE  
DEPARTMENT OF BIOPHYSICS  
PART- OR FULL-TIME  
TECHNICIAN**

Applications are invited for a post available immediately for a Technician with experience of either heteroduplex analysis using the electron microscope or restriction endonuclease mapping and sequencing of DNA.

The post is funded by a research grant and salary will be on Grade 5 scale, £3,998 per annum to £4,580 per annum inclusive.

Candidates should write with curriculum vitae and the names of two referees to: The Head Clerk (Ref: 217808/N), King's College, London, Strand, WC2R 2LS. 2065(A)

**KING'S COLLEGE HOSPITAL  
MEDICAL SCHOOL  
(University of London)**

Denmark Hill

London SE5 8RX

LIVER UNIT

Applications are invited for the position of

**RESEARCH ASSISTANT/  
FELLOW**

in this busy multi-disciplinary unit from candidates with experience in cell membrane biology, immunochemistry or protein biochemistry, to work on human liver cell surface antigens.

Salary will be on University of London scales, according to qualifications and experience.

Please apply, giving full curriculum vitae and the names and addresses of two referees to the Secretary of the Medical School at the above address, from whom further details may be obtained. Closing date: June 29, 1979. 2002(A)

**THE MIDDLESEX HOSPITAL  
MEDICAL SCHOOL  
(University of London)**

Applications are invited for the post of  
**RESEARCH ASSISTANT**

to work on the cellular basis of cartilage growth. This post will be supported by the Medical Research Council for three years, commencing October 1, 1979.

Salary up to £5,304 per annum (including London Allowance) depending on age and experience.

Applications, together with the names of two referees, to Professor L. Wolpert, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, Cleveland Street, London W1P 6DB. 2067(A)

**WESTMINSTER  
MEDICAL SCHOOL  
RESEARCH ASSISTANT**

An organic Chemist or Biochemist is needed by a small team working on pigment changes in human disease. The post would be particularly suitable for a recent graduate or for someone graduating this year. The successful applicant would be required to develop methods for the isolation and assay of pigment intermediates from the body fluids of patients undergoing treatment and in the culture fluid from cells grown in tissue culture. Post available for one year initially.

Salary on the Whitley Council Scale for Hospital Biochemists.

Applications, with curriculum vitae and the names of two referees should be made to Professor J. R. Hobbs, Department of Chemical Pathology, Westminster Medical School, 17 Page Street, London SW1P 2AR. Closing date will be June 24, 1979.

Please quote: Reference KBC. 2027(A)

**Cancer Research Campaign  
Laboratories**

**UNIVERSITY OF  
NOTTINGHAM**

vacancy exists in the C.R.C. laboratories in Nottingham for a

**POSTDOCTORAL SCIENTIST**

to work on the biochemistry of tumour surface membranes with special reference to studies into the synthesis and turnover of tumour-associated antigens.

The post is offered for a period of 12 months from August 1979.

Applications in writing, quoting the names of two referees, to the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD, not later than June 1979. Ref: 696. 1093(A)

## Leptospira Reference Laboratory

# Senior Grade Microbiologist

Applications for the above post are invited from graduate microbiologists with a wide experience in medical microbiology. The successful applicant will be required to assist with the routine work of the laboratory but in addition he/she will have the opportunity to contribute to the research and development programme.

Previous experience in microbiological research is essential, it need not have been in leptospirosis, although some knowledge of immunology would be an asset.

Salary scale £5,451 to £6,837 plus £354 London Weighting. N.H.S. Terms and Conditions of Service.

For further information write to: Dr J. D. Coghlan, Leptospira Reference Laboratory, Central Public Health Laboratory, Colindale, London NW9 5DX.  
2021(A)

**PH  
LS**

Public Health Laboratory  
Service Board.

## DEPARTMENT OF NEUROCHEMISTRY MAX-PLANCK-INSTITUT FÜR PSYCHIATRIE MUNICH

The Max-Planck-Gesellschaft offers

# YOUNG SCIENTISTS

the opportunity to set up their own research group in the above department.

Applicants should have already accomplished internationally recognised research within the general area of neurobiology, especially in membrane-receptor biochemistry, neurogenetics, neuroimmunology or neuroendocrinology.

Appointments will be limited to 5 years, the salary being within the scale AH3/C3. (about 50-55.000 DM per annum).

Each group will be able to grant post-doc-/doctoral scholarships to German and foreign scientists; it will also be provided with its own laboratory, inclusive technical staff, appropriate equipment and adequate running costs.

Applications should contain a tabular curriculum vitae, a list of publications, and a short description of scientific work both achieved and intended, and should be submitted to the

Max-Planck-Gesellschaft zur Förderung der Wissenschaften e.V.-Generalverwaltung-III a 4-Postfach 647, 8000 München 1, before September 30, 1979.  
W148(A)

## UNIVERSITY OF THE WITWATERSRAND Johannesburg

Applications are invited from suitably qualified persons for appointment to the following posts:

### DEPARTMENT OF GEOPHYSICS

#### SENIOR LECTURER/ LECTURER IN GEOPHYSICS SENIOR LECTURER/ LECTURER IN APPLIED GEOPHYSICS

The Department offers third-year level and Honours level courses in Geophysics, as well as the degree of B.Sc. (Eng.) in Applied Geophysics. The two appointees will be responsible for lectures, laboratory classes and supervision of research. Applicants could come from a range of professional disciplines but should have qualifications and experience in one or more of the major areas: geomagnetism, gravity, seismology, EM and galvanic methods, isotopes and heat flow, rock deformation science.

The salary ranges are:

SENIOR LECTURER: R11,400 to R15,600 per annum. LECTURER: R8,100 to R13,200 per annum (£1 equals R1.75 approx.).

### BERNARD PRICE INSTITUTE OF GEOPHYSICAL RESEARCH PHYSICIST/GEOPHYSICIST

The Institute seeks a physics or geophysics graduate for a post in its Isotope Geophysics laboratory. This laboratory undertakes geochronological and isotope evolution studies using the U-Pb, Rb-Sr, Sm-Nd methods and is equipped with two modern mass spectrometers utilising digital and computer facilities plus extensive ancillary facilities. The appointee would be responsible for maintenance and development of the mass spectrometers but would also become involved in a research project, the results of which could be used for gaining a higher degree. Some knowledge of digital and computer techniques is essential, but further training could be arranged; previous geological training would be advantageous but not essential. The salary will lie in the range of R5,850 to R13,200 per annum.

### STRUCTURAL GEOLOGIST

A geologist is required for field mapping and microscope study of deformed rocks in the Vredefort dome basement. A team is studying radial profiles, which probably extend 'down' a ~15 km-thick section of Archaean crystalline crust, into the middle crust. Applicants with an Hons. degree may use research results for a higher degree. The starting salary will lie in the range R4,950 to R9,000 per annum.

The appointees will be placed at an appropriate notch on the salary scales, according to qualifications and experience.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion, or colour. Further particulars relating to this practice and to the above posts are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001 South Africa, with whom applications should be lodged. Applications in writing, giving full personal and career details, including telephone number, and the names and addresses of three persons who may be called upon to act as referees, should be lodged with the Registrar by July 6, 1979. 2040(A)

## UNIVERSITY OF DUNDEE

Applications, from candidates who hold or are about to obtain a good Honours degree in Biochemistry or related subject, are invited for appointment as a

### RESEARCH ASSISTANT

to work with Dr P. R. Baker, in the University Department of Surgery at Ninewells Hospital and Medical School, on a study of the effects of cholestasis on cellular transport and protein binding of bile salts by the liver.

The appointment is supported by a S.H.H.D. grant and will be available for three years from September 1, 1979, or some other agreed date. Initial salary at an appropriate point within the range £3,689 to £4,232 (to be reviewed from October 1, 1979). Superannuation under U.S.S. Possibility of registration for a higher degree.

Applications, quoting reference EST/54/79J and containing full details of qualifications and experience and the names of three referees, should be sent to The Secretary, The University, Dundee DD1 4HN by July 5, 1979.

Informal enquiries may be made to Dr P. R. Baker, Department of Surgery, Ninewells Hospital and Medical School, Dundee. 2038(A)

## UNIVERSITY OF SALFORD DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY POSTDOCTORAL RESEARCH FELLOW

required for a project sponsored by the Science Research Council entitled 'SN<sub>2</sub> Reactions Involving Organocuprate Reagents' under the supervision of Dr S. M. Roberts. The appointment is tenable for one year in the first instance, commencing October 1, 1979.

Commencing salary within the range: £3,883 to £4,382 per annum (under review), U.S.S.

Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (tel: 061-736 5843, ext. 215) to whom completed applications should be returned by not later than June 21, 1979, quoting reference no. CH/258/N. 2003(A)

## university of wales university college of swansea

### Research Demonstrator

Applications are invited for the vacancy of Research Demonstrator in the Department of Botany and Microbiology. Applicants should have a Ph.D. degree acquired by research on some aspect of either Botany or Microbiology. The duties will include demonstrating to practical classes, conduct of tutorials and possibly some lecturing. The successful candidate will be expected to conduct original research and ample time will be left for this.

The appointment, which will be for one year in the first instance from October 1, 1979, will be on a scale up to £4,910 per annum. Further particulars and application forms (2 copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by FRIDAY, JUNE 22, 1979. 2059(A)

**UNIVERSITY OF  
EDINBURGH  
DEPARTMENT OF PHYSICS  
RESEARCH ASSOCIATE/  
FELLOW**

**in Neutron Scattering**

Applications are invited for the post of research associate/fellow to take part in a programme in neutron-scattering experiments associated with the study of structural phase transitions. This project will involve both elastic scattering for high-accuracy, high-resolution studies of crystal structure, and inelastic scattering to make parallel investigations of crystal dynamics. Most experimental work in the immediate future will be at the Institut Laue-Langevin, Grenoble.

The appointment, for up to three years, commences October 1979 (or later by arrangement) at a salary according to age and experience on scale 1A, Superannuation under F.S.S.U./U.S.S. Applicants should have, or be about to obtain, a Ph.D.

Applications with the names of two referees and a statement of applicant's interests and career to date to Dr R. J. Nelmes, Department of Physics, University of Edinburgh, Mayfield Road, Edinburgh EH9 3JZ, to arrive as soon as possible. Further details on request. Please quote Reference 5027. 2011(A)

**NUFFIELD  
LABORATORIES  
OF COMPARATIVE  
MEDICINE  
INSTITUTE OF ZOOLOGY  
ZOOLOGICAL SOCIETY  
OF LONDON**

A recently qualified

**POSTDOCTORAL  
RESEARCH FELLOW**

required for studies on lipid metabolism of the brain with special reference to the role of essential fatty acids and prostaglandins. The successful candidate would be expected to work with a group studying nutrition and the development of the nervous and vascular systems. Experience in lipid biochemistry is essential.

The post will be tenable for 3 years and will carry a salary related to the London University Lecturer scale at a point appropriate to age and experience with U.S.S./J.S.D.P.S. benefits.

Applications in writing to Assistant Establishment Officer, Zoological Society of London, Regents Park, London NW1 4RY. 2053(A)

**UNIVERSITY OF  
SALFORD  
DEPARTMENT OF BIOLOGY  
RESEARCH ASSISTANT  
OR FELLOW**

Applications are invited from biologists/physiologists to assist with a study sponsored by the Agricultural Research Council of respiratory/metabolic physiology in vertebrates. An appointment will be made at the postdoctoral or graduate level depending on qualifications and is tenable for up to 3 years. Informal enquiries concerning the appointment may be made to Dr J. H. Brackenbury, Department of Biology.

Salary within the range: £3,689-£4,776 per annum. U.S.S. benefits.

Application forms are obtainable from the Registrar, University of Salford, Salford M5 4WT (tel: 1-736 5843, ext. 215) to whom completed applications should be returned by June 25, 1979, quoting Ref. No. B/92/N. 2055(A)

**THE RESEARCH  
ORGANISATION OF  
SYNTHELABO**

An Internationally recognised European Pharmaceutical Group located in Paris requires a

**SENIOR TOXICOLOGIST**

to lead a team responsible for various projects within a developing toxicology group in the Department of Biology.

The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

Applicants can be either male or female and should be a Ph.D. with at least five years' postdoctoral experience in toxicology and preferably with industrial experience as well. Suitably qualified veterinarians and pharmacists with relevant experience will also be considered for the post.

Candidates should possess a good working knowledge of French and English and should also be conversant with the G.L.P. regulations for toxicology.

A realistic salary can be expected and relocation assistance will be available together with other financial benefits. All applications will be treated in the strictest confidence and should be sent directly to M R. J. Brault at the following address:

Synthelabo  
58 Rue de la Glaciere  
75013 Paris W151(A)

**THE ROYAL VETERINARY  
COLLEGE**

University of London

Division of Clinical Studies

DEPARTMENT OF

ANIMAL HUSBANDRY

AND HYGIENE

**RESEARCH ASSISTANT**

Applications are invited, preferably from veterinary or animal science graduates, for the above post of Research Assistant, which is expected to be for three years supported by grant from the Ministry of Overseas Development, to take part in a study of nutritional and environmental factors influencing reproduction in ewes and growth of lambs. This is part of a project being undertaken in Colombia and the work will include a laboratory analysis of samples from Colombia.

The post is based at Boltons Park, near Potters Bar, Herts.

Starting salary between £4,191 and £5,278 (including London Allowance) according to qualifications and experience.

Application form from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone 01-387 2898. 2041(A)

**New Zealand  
UNIVERSITY OF  
CANTERBURY  
Christchurch**

**VISITING LECTURER  
IN CHEMISTRY**

Applications are invited for a Visiting Lectureship in Chemistry tenable for one year. The appointment is to be taken up as early as possible in 1980. It is anticipated that the appointee will have completed a Ph.D. and show evidence of strong research interest in some particular field of Chemistry.

The emolument for this position is on a scale from NZ\$11,894 to NZ\$14,615 per annum. When the salary is being decided, due account will be taken of the appointee's travel costs.

Applications close on **July 15, 1979**. Further particulars and Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 1096(A)

**CSIRO AUSTRALIA**

**Postdoctoral Research Fellow  
Australian Numerical Meteorology  
Research Centre  
Melbourne, Victoria**

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of who are research and professional scientists—located in Divisions and Sections throughout Australia.

**Field:** Mathematical Modelling of Climate.

**General:** The Australian Meteorology Research Centre is a joint venture of the CSIRO and the Department of Science (Bureau of Meteorology). The Centre's research consists of studies of the behaviour of the earth's atmosphere, with emphasis on general circulation, directed towards improvement in the accuracy and time scale of weather forecasting, and towards improvement in understanding the distribution and variations of climate on the earth.

In this context the Centre is seeking further support for its climatic activities. Currently the Centre has a number of large scale general circulation models of the earth's atmosphere in use, as well as a more limited modelling involvement in oceanography. The research programme with these models includes detailed simulation of the general circulation, climatic studies, air-sea interaction experiments, investigation of the mechanisms of drought, geophysical experiments and atmospheric chemistry and pollution studies. Additional effort is to be committed to climatic studies using an advanced two level general circulation model developed at the Centre.

**Duties:** Initially to collaborate in experiments with a two level model involving multi-annual integrations with and without coupled oceans with a view to understanding the underlying mechanisms and causes of interannual variability. To formulate appropriate research programmes using this or other models in accordance with the research aims of the Centre.

**Qualifications:** Applicants should have a PhD in dynamical meteorology or an associated field or postgraduate experience of equivalent standard and duration. As considerable initiative is encouraged and expected in the implementation of new programmes, applicants should be highly self-motivated and in particular of high creativity.

**Salary:** Research Scientist \$15,422—\$18,904 pa. or Senior Research Scientist \$19,572—\$22,405 pa. Scientists with considerable experience and outstanding ability should not be deterred from applying as appointment at a higher level and salary would be considered.

**Tenure:** Initially three years with the possibility of an extension of a further two years subject to mutual agreement.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 424/029 should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 6th July, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 1089(A)

**UNIVERSITY OF ALBERTA**

**FACULTY OF PHARMACY AND PHARMACEUTICAL SCIENCES**

Applications are invited for a full-time tenurable appointment, effective July 1 or September 1, 1979, in Pharmacaceutics.

The position requires an individual trained at the Ph.D., Pharm.D. level or equivalent and having a special interest and expertise in dosage form design, development and evaluation. Responsibilities include (1) development of an independent research programme in pharmacaceutics, and (2) contribution to the undergraduate and graduate teaching programmes in physical pharmacy and pharmaceutical technology. Appointment will normally be at the rank of assistant professor. Appointment at a higher rank may be considered based upon experience.

The University of Alberta is an equal opportunity employer and offers excellent fringe benefits.

Interested candidates should send a letter of application, a curriculum vitae and the names of three references to:

Dean G. R. Van Petten  
Faculty of Pharmacy and Pharmaceutical Sciences  
Rm. 3118/Dentistry/Pharmacy Centre  
University of Alberta  
Edmonton, Alberta T6G 2N8 W147(A)

## Science Research Council SPACE SCIENCE POST FOR APPLETON LABORATORY/ RUTHERFORD LABORATORY

The SRC requires a person to join its space science team which is concerned with astrophysics and geophysics research and with space project management in support of University programmes. For the first five years of the appointment the selected candidate will be given unpaid leave of absence to enable him/her to take up a post in Oxford University where he/she will be the deputy to the Head of the Department of Atmospheric Physics with particular responsibility for administration and day-to-day organisation of research projects involving satellite, balloon, and aircraft mounted instrumentation. During this period the person appointed will also be expected to pursue research in some aspect of atmospheric physics and to assist with the teaching and supervision of graduate students. At the end of this period the person would be expected to head a team working in some branch of Atmospheric Physics or its management within the Appleton/Rutherford Laboratory at Chilton.

Candidates should have had wide experience of Atmospheric Physics using space research and have had a successful record in major space project management. He/she should be accustomed to working with an academic community.

The post is graded Principal Scientific Officer, with a salary on the scale £6,609—£8,461 (currently under review), with a non-contributory superannuation scheme. Whilst at Oxford University, the successful candidate will be placed on Grade III in the Structure for Research Staff, which has a salary scale of £8,182—£10,097.

Applications, including a full curriculum vitae, should be sent to Mrs A. P. Roythorn, Science Research Council, P.O. Box 18, North Star Avenue, Swindon SN2 1ET, Wiltshire, to arrive before 22nd June, 1979. 2062(A)

## Graduate – Biochemistry

We have a vacancy for an Experimental Officer in the Biochemistry Section of our Chemistry Group. The person we are seeking should have a degree or HNC in Biochemistry or Botany, with a good knowledge of plant biochemistry generally and a sound understanding of photosynthesis specifically. Experience with a range of techniques associated with photosynthesis research and also some experience of enzymology is desirable. He or she will respond to a PhD Biochemist studying biochemical mechanisms involved in herbicide action. This will involve short term research aimed at optimizing chemical structures in *in vitro* tests, as well as longer term research to gain a more precise understanding of the interaction between plants and inhibitors. We offer good salaries, profit sharing scheme and pension fund. A Staff Restaurant and Recreation Club are on site. Subsidised coaches run from Jealott's Hill, Bracknell and Maidenhead. If you are interested in applying for this vacancy please apply to: S R Stephenson, Personnel Officer, ICI Plant Protection Division, Bracknell, Berkshire. 1087(A)

**Plant Protection  
Division**

### UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF GENETICS POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the above post (salary scale £4,232 to £7,145) from applicants who have or are about to submit for the degree of Ph.D. in any of the following subject areas: Virology, Biochemistry, Genetics, Microbiology or other related field.

The post will be funded from a Wellcome Trust Grant and is tenable for a two-year period (starting date negotiable).

The research project involves characterisation and mapping of peptides obtained from virus proteins using a new analytical procedure. A research technician will assist the successful applicant in this work.

Written applications together with the names and addresses of three referees should be sent to Dr A. C. R. Samson, Department of Genetics, Ridley Building, The University of Newcastle upon Tyne, NEWCASTLE UPON TYNE NE1 7RU. Closing date for applications six weeks after appearance of this advertisement. 2035(A)

### UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY LECTURER IN NUTRITION

Applications are invited from suitably qualified graduates for a Lectureship in Nutrition in the Division of Nutrition and Food Science of the Biochemistry Department. Preference will be given to applicants with post-graduate experience in human nutrition.

Salary will be within the range £4,232 to £8,452 per annum depending upon qualifications and experience (£4,333 to £8,992 per annum as from October 1, 1979). Superannuation is under U.S.S. conditions.

Further particulars about the post may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH, or tel: Guildford 71281, ext. 452.

Applications from men or women in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent to the above by June 29, 1979. 1090(A)

### THE UNIVERSITY OF WINNIPEG DEPARTMENT OF BIOLOGY MICROBIOLOGIST

Applications are invited for a sessional appointment at the level of Assistant/Associate Professor to develop and teach courses in Microbial Taxonomy and Immunology and undertake other assigned duties.

The position will be renewable for up to three years. Starting date September 1, 1979. Rank and salary dependent on qualifications and experience. Send curriculum vitae and the names of three referees to: Dr R. A. Woods, Biology Department, The University of Winnipeg, Winnipeg, Manitoba, Canada R3B 2E9. W150(A)

### GLASSHOUSE CROPS RESEARCH INSTITUTE requires SCIENTIFIC OFFICER IN PLANT PHYSIOLOGY DEPARTMENT

for research programme on properties and function of phytochrome. Appointment in Scientific Officer grade. Salary £2,839 to £4,415 (under review). Applicants should preferably have honours degree in Botany, Plant Physiology or Plant Biochemistry, with experience in biochemical techniques. Non-contributory superannuation scheme.

Further details and application form on request from Secretary, G.C.R.I., Worthing Road, Rustington, Littlehampton, W. Sussex BN16 3PU. Closing date: June 20. 2018(A)

### SHEFFIELD CITY POLYTECHNIC DEPARTMENT OF CHEMISTRY CHEMISTRY RESEARCH POSTS

Applications are invited for the following posts to be taken up in 1979. The post holders will be expected to seek registration for M.Phil./Ph.D. degrees of C.N.A.A.

#### POLYMER CHEMISTRY:

##### RESEARCH ASSISTANTSHIP

The successful applicant will work with Dr G. C. Corfield and other members of a Polymer science and technology research group on the synthesis and radiation stability of silicone elastomers. This is a salaried appointment for the fixed term of three years.

Salary: £2,916 to £3,330.

Starting date: September 1, 1979.

#### ANALYTICAL CHEMISTRY:

##### S.R.C. C.A.S.E. STUDENTSHIP

The project concerns trace metal speciation in environmental and other samples by directly coupled chromatography — atomic spectroscopy. The Studentship is in collaboration with Pye-Unicam, Cambridge, and the academic supervisors are Dr L. Ebdon and Dr D. A. Leathard. The S.R.C. award is to be supplemented by £500 per annum. Normal S.R.C. conditions of eligibility apply.

Starting date: October 1, 1979.

Requests for an application form in writing only please to the Recruitment Section of the Personnel Department, Sheffield City Polytechnic (Dept. N), Halfords House, Fitzalan Square, Sheffield S1 2BB. Completed forms should be returned by July 1, 1979. 2013(A)

### UNIVERSITY OF SALFORD DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY POSTDOCTORAL RESEARCH FELLOW

required for work on an S.R.C. sponsored project, 'The Synthesis and Evaluation of Novel Photo-activated Reagents for use in Biological Membrane Studies', under the supervision of Professor H. Suschitzky. The research is suitable for a candidate holding, or expecting to hold a Ph.D. in Organic Chemistry or Biochemistry. Post tenable for up to 2 years.

Salary range: £4,232 to £4,770 per annum. U.S.S. benefits.

Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (tel 061-736 5843, ext. 215) to whom completed applications should be returned quoting Ref. No CH/259/N. 2056(A)

### UNIVERSITY OF DUBLIN Trinity College LECTURER IN BIOCHEMISTRY

Applications are invited for the above post in the Department of Biochemistry, Trinity College Dublin.

Salary scale: £4,317 to £8,487 per annum.

Appointment may be made within the range commensurate with the qualifications and experience of the successful candidate. There is a non-contributor pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941, Ext. 1678 or Ext. 1775.

The closing date for receipt of applications will be Thursday June 28, 1979. W149(A)

**THE UNIVERSITY OF  
LEEDS**  
**DEPARTMENT OF INORGANIC  
AND STRUCTURAL  
CHEMISTRY**

Applications are invited for  
a temporary post of  
**POSTDOCTORAL**

**RESEARCH FELLOW**  
from inorganic or bio-chemists.

Candidates should already possess, or expect to receive within the next few months, a Ph.D. degree. Experience in mechanistic studies would be valuable. The appointee will take part in a project, supported by S.R.C., on electron, supported by S.R.C., on copper proteins, iron-sulphur proteins and cytochrome c. Some collaboration and interchange with Professor R. G. Wilkins in the U.S.A. may be involved. The appointment will be made for a fixed period of up to 2 years commencing October 1, 1979.

Starting salary in the range £4,333 to £4,910 on the 1A scale for Research and Analogous Staff (£4,333 to £7,521) (under review), according to age, qualifications and experience.

Enquiries should be addressed in the first instance to Dr A. G. Sykes, Department of Inorganic and Structural Chemistry, The University, Leeds LS2 9JT (Tel: 0532-31751, ext. 6068/6057).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 44/7. Closing date for applications: July 2, 1979.

2017(A)

**UNIVERSITY OF GLASGOW**  
**CHEMISTRY DEPARTMENT**  
**GC-MS UNIT**

(Revised Advertisement)

Applications are invited for a  
**POSTDOCTORAL**

**RESEARCH APPOINTMENT**

able for two years from October '81, or investigations on biologically active steroid/cholesterols and related compounds by GC-MS and ancillary techniques. The Unit is equipped with KB 9000 and DuPont 21-490F I/EI instruments, either of which can be used on-line to a VG 2035 data System.

Starting salary in the range £4,333 to £4,910 (the latter for age 26) of the scales for Research and Analogous Staff (1A) with U.S.S. benefits. Further details are available from Professor C. J. W. Brooks, Chemistry Department, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 65M.

2010(A)

**LECTURER  
IN  
BIOCHEMISTRY**

Applications are invited for the above post in the Department of Biochemistry, Trinity College, Dublin.

Salary scale: £4,317 to £8,487 per annum.

Appointment may be made within range £4,317 to £5,492 per annum, a point commensurate with the qualifications and experience of the successful candidate.

There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 941, ext. 1678 or ext. 1775.

The closing date for receipt of applications will be **Thursday, June 28, 1979**.

2061(A)

**NATIONAL  
UNIVERSITY OF LESOTHO**  
Applications are invited for the post of  
**SENIOR LECTURER/  
LECTURER**

in Organic, Physical Organic or  
Physical Chemistry

to teach at the General B.Sc. degree level.

Salary scales: Senior Lecturer R7,473 to R8,433 per annum; Lecturer R5,493 to R7,527 per annum. (£1 sterling=R1.72.) The British Government may supplement salary in range £1,644 to £2,508 per annum (sterling) for married appointee or £570 to £1,410 per annum (sterling) for single appointee (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Superannuation: Appointees on contract terms receive 25% gratuity in lieu of superannuation for the first two years of the contract, rising to 27½% and 30% for each subsequent and similar period of service. 15% inducement allowance for expatriates not qualifying for any supplementation aid scheme. Accommodation is available at reasonable rentals. Family passages; baggage allowance; education allowance; vacation and study leave; medical aid scheme.

Detailed applications (2 copies) with curriculum vitae and naming three referees by July 18, 1979, to the Administrative Assistant (Appointments) NUL, Roma, Lesotho, Africa.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

2000(A)

**UNIVERSITY OF WARWICK**  
**POSTGRADUATE  
RESEARCH ASSOCIATE**

in the

**DEPARTMENT OF  
CHEMISTRY AND  
MOLECULAR SCIENCES**

Applications are invited to the S.R.C. funded post of Postgraduate Research Associate to work with Dr O. W. Howarth on a <sup>13</sup>C nuclear magnetic resonance study of the physical dynamics of biomolecules and macromolecules. Candidates should hold a good honours degree in chemistry or biochemistry. A suitably qualified candidate will be permitted to register for a higher degree on appointment. The post is tenable for three years with a starting salary up to £4,232 per annum on the Research Range 1B scale £3,689 to £5,321 per annum depending on age and experience. Applications, together with the names of two referees, should be received not later than June 29, 1979, by the Academic Registrar, University of Warwick, Coventry CV4 7AL. Please quote Ref. No. 44/A/79.

2042(A)

**QUEEN MARY COLLEGE**  
**University of London**  
**ASTRONOMY—  
APPLIED MATHEMATICS  
POSTDOCTORAL  
RESEARCH ASSISTANT**

required from October 1, to work with Professor I. W. Roxburgh and Dr S. J. Schwartz on an S.R.C. supported project on plasma physics of the solar wind. Applicants should have experience in an area of plasma physics. Appointment for 2 years, with possibility of extension for third year.

Initial salary in range (under review) £4,835 to £5,990 per annum (including London Allowance).

Applications, including age, qualifications, experience and names of 2 referees, should be sent to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS.

1099(A)

**DIRECTOR AND PROFESSOR  
MEDICAL BACTERIOLOGIST**

**ROBERT KOCH INSTITUTE  
FEDERAL HEALTH OFFICE**

**BERLIN, FEDERAL REPUBLIC OF GERMANY**

The Federal Health Office is a superior Federal authority. Among its terms of reference are practice-oriented research, advisory and executive tasks, preparation of expertise as well as work on medical statistics in the field of Public Health. Its aims are the promotion of consumer protection in respect of health, reduction of health hazards resulting from the environment, detection of causes, early recognition, and control of diseases as well as drug safety. 1,400 people are employed, among them 350 scientists.

Applications are invited for a post involving interesting, responsible and independent work.

**Responsibilities:** As chief bacteriologist, the appointee is responsible for the Enterobacteriaceae Unit which has the status of a National Salmonella and Vibrio Reference Laboratory. He is expected to supervise the staff, to carry on Public Health tasks linked to the diagnostic and epidemiological work of the laboratory and to perform scientific research for the promotion of diagnostic development in the field of enterobacteriaceae with special reference to enterotoxinogenic germs.

**Qualifications:** M.D. or equivalent in microbiology, clinical bacteriologist preferred. Several years' experience in bacteriology and/or diagnosis of bacterial infections with special reference to enteropathogenic bacteria. The candidate is expected to present a list of scientific publications on relevant subjects.

**Languages:** Excellent knowledge of English or good working knowledge of other languages such as French or German.

**Initial salary:** 60,000 DM/year. The Office will assist the successful applicant in the procurement of housing. Allowance for temporary separation from family is granted under applicable regulations.

Applications with curriculum vitae, photograph, brief outline of professional career, copies of credentials, and a list of publications should be sent by July 16, 1979, to the

**PRESIDENT OF THE FEDERAL HEALTH OFFICE**  
**Postfach: D-1000 Berlin 33**

quoting reference number 367 01.

For further information please call: (030) 8308 569 (Herr Pankonin).

W145(A)

**ULSTER POLYTECHNIC**  
**RESEARCH OFFICER**

(TWO-YEAR APPOINTMENT)

Salary Scale: £3,732 to £4,632 (under review)

A Research Officer is required to work in the Chemistry Division of the School of Physical Science on one of the following projects:

- Electrochemical fixation of carbon dioxide;
- Synthesis and testing of fungicides;
- Investigation of the Starch enzymology of Bacillus Macerans.

Applicants must have a good Honours degree or equivalent in Chemistry. A higher degree with appropriate research experience will be an added advantage.

The Polytechnic is a direct grant institution with an independent Board of Governors. It opened in 1971 and has a student population of some 7,500. It has extensive new purpose-built accommodation, including 750 residential places on the 114-acre campus overlooking the sea at Jordanstown, a pleasant and quiet residential area. There is a scheme of assistance with removal.

Further particulars and application forms which must be returned by June 25, may be obtained by telephoning Whiteabbey (0231) 65131, ext. 2243 or by writing to:

The Establishment Officer, Ulster Polytechnic, Shore Road, NEWTOWNABBEY, Co. Antrim BT37 0QB.

2025(A)

## CSIRO AUSTRALIA

### Postdoctoral Research Fellow

#### Division of Forest Research Queensland Regional Station Atherton, Queensland

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of who are research and professional scientists—located in Divisions and Sections throughout Australia.

**Field:** Forest Soils Research.

**General:** The Division has a small group located at Atherton in North Queensland undertaking research in aspects of rainforest botany and ecology. Atherton lies within the main belt of tropical rainforest in northeastern Australia and is well situated as a base for field research with a wide variety of rainforest types in the immediate vicinity.

**Duties:** To initiate and undertake research relating to the influence of soil properties on the distribution of rainforest plant species and the effects of various forest management alternatives on the stability of rainforest soils. It is envisaged that the work will be carried out in co-operation with other members of the Station and soil scientists from the Division of Soils located in Townsville.

**Qualifications:** A Ph.D. or equivalent qualification in a relevant field, preferably soil physics.

**Salary:** Research Scientist/Senior Research Scientist \$15,422—\$22,405 p.a.

**Tenure:** 5 years superannuation available.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 1050/131 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 6th JULY, 1979.

Applications in U.S.A. and Canada should be sent to:—  
The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

1088(A)

### M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital) Watford Road, Harrow, Middlesex HA1 3UJ

We require a

#### Ph.D. PHARMACOLOGIST

with experience in experimental cancer chemotherapy or in evaluating toxicity of antitumour drugs in experimental cancer chemotherapy. This work will be carried out under a grant awarded for two years by the National Institute of Health. This appointment will therefore be for two years on a salary scale starting from £3,883 to £6,080 per annum plus £502 London Allowance.

Application form obtainable from Mrs J. Tucker-Bull, 01-864 5311, ext. 2685. Please quote Ref. 111/1/NIH/SC. Closing date: June 22, 2008(A)

### THE ANIMAL VIRUS RESEARCH INSTITUTE Pirbright, Woking Surrey GU24 0NF MICROBIOLOGIST/ IMMUNOLOGIST

Applications are invited for a microbiologist/immunologist to work on the antigen and antibody relationship in foot-and-mouth disease and possibly other viruses which show marked antigenic variation. Recent work has established the possibility of production of monoclonal antibodies and it is proposed to intensify work on this topic. Candidates should have a good honours degree and at least four years' postgraduate experience in immunology or virology.

The post is in the S.S.O. grade £5,154 to £6,898, under review). House available for suitable married applicant. Non-contributory superannuation scheme.

Application forms and further particulars from the Secretary.

2028(A)

### UNIVERSITY OF SOUTHAMPTON

#### MEDICAL ONCOLOGY UNIT

Applications are invited for the position of Postdoctoral Research Fellow in the above Unit. The person appointed will work on the isolation of cytoskeletal proteins and their interaction with the cell surface, in close cooperation with a group interested in cell adhesion and with others interested in clinical aspects of cancer research. Applicants should either be about to obtain or have recently obtained a Ph.D. in Biochemistry or some related discipline. Experience of protein biochemistry, or immunology would be advantageous. The appointment will be for three years.

Salary Range: £4,333 to £5,488 per annum. U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, not later than June 22, 1979. Please quote reference 1069/R. 2044(A)

### International Laboratory for Research on Animal Diseases I.L.R.A.D.—Nairobi—Kenya RESEARCH ASSISTANT

To work on the Immunology and Parasitic diseases. There are three vacancies for research assistants in the laboratory of the Director of I.L.R.A.D. The research assistants should be qualified and should have experience on tissue culture, immunology or parasitic diseases.

#### TERMS:

The salary will depend on age and experience. Perquisites include moving allowance, housing and commutation allowances, medical and retirement benefits. Applications, with curriculum vitae, and the names of three referees should be submitted to

The Director

I.L.R.A.D.

P.O. Box 30709

NAIROBI—KENYA

To reach him not later than June 28, 1979. W137(A)

### UNIVERSITY OF CAMBRIDGE BIOMETRY

vacant

### UNIVERSITY DEMONSTRATORSHIP in the DEPARTMENT OF APPLIED BIOLOGY

to support teaching and research in Biometry with special emphasis on use of the University computer. Good Honours degree in Mathematics, Statistics or Computer Science and/or postgraduate experience of biometrical analysis and computer-programming.

Salary in scale £4,505 to £5,591, pensionable. Limited contribution to removal expenses.

Further details from and applications including full personal particulars, list of publications and names and addresses of not more than three referees to the Secretary, Faculty of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, not later than July 7, 1979. 2064(A)

### CENTRAL MIDDLESEX HOSPITAL DEPARTMENT OF GASTROENTEROLOGY RESEARCH ASSISTANT

A Research Assistant is required work on a Research Programme concerned with clinical nutrition. The work is concerned with investigating the pathophysiology of diarrhoea that occurs during Enteral Nutrition.

The post is for two years at an initial salary of £3,689 (plus £354 London Allowance). It is hoped that the appointee will register for a higher degree.

Applications and enquiries should be sent to Dr D. B. A. Silk, Department of Gastroenterology, Central Middlesex Hospital, London NW10 not later than July 1, 1979.

2048(A)

### UNIVERSITY OF LIVERPOOL ORTHOPAEDIC AND ACCIDENT SURGERY TECHNICIAN

for research project concerning the biological approach to replacement of arthritic joints. Facilities are available within the department for cartilage and bone cell culture. Previous experience of immunological techniques desirable, but training given. Candidates must possess H.N.C. or an appropriate equivalent qualification and have had several years laboratory experience. Salary within a range up to £4,056 per annum, according to qualifications and experience.

Application forms available from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref. RV/628/N. 2046(A)

### PRESTON POLYTECHNIC

Applications are invited for the post of

### PRINCIPAL LECTURER IN ASTRONOMY AND DIRECTOR OF THE POLYTECHNIC OBSERVATORIES

Salary: Principal Lecturer £7,047 to £7,818 (bar) to £8,844 under review.

Further particulars and application forms are available from the Personnel Officer, Preston Polytechnic, Corporation Street, Preston PR1 2TQ, to whom completed applications should be returned within 14 days of this advertisement. 2034(A)

### UNIVERSITY OF MASSACHUSETTS

Three positions in protein bio synthesis available immediately in the Department of Biochemistry.

1. POSTDOCTORAL to work on elucidating the topography of ribosomal binding sites for initiation factors and tRNA by photochemical labelling.

2. POSTDOCTORAL to work on the analysis of ribosome assembly reactions by photoaffinity and fluorescence techniques.

3. ASSISTANT PROFESSOR RESEARCH ASSOCIATE to teach course in molecular biology and to participate in research on ribosome structure and function, with emphasis on the physicochemical characterisation of protein-nucleic acid interactions.

Experience in protein synthesis, nucleic acid chemistry desirable. Appointments of one to three year can be arranged. Send resume, in including the names of three reference and position applied for, to Dr I Schwartz or Dr R. A. Zimmermann Department of Biochemistry, University of Massachusetts, Amherst Massachusetts 01003, U.S.A.

An Affirmative Action/Equal Opportunity Employer. W153(A)

### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)  
Keppel Street WC1E 7HT

#### DEPARTMENT OF HUMAN NUTRITION

CLINICAL NUTRITION AND  
METABOLISM UNIT

ST. PANCRAS HOSPITAL

#### A POSTDOCTORAL RESEARCH FELLOW

is required in September 1979 to work for up to two years on a project sponsored by the Medical Research Council for studies on the regulation of protein synthesis and breakdown in animal tissues.

The salary is in the range £4,360 to £7,145 (under review) plus £50 London Weighting.

Applications, consisting of curriculum vitae and naming two referees, should be addressed to Professor J. C. Waterlow at the C.N.M.U. 4 St. Pancras Way, London NW1. 2066(A)

### KINGSTON POLYTECHNIC RESEARCH OPPORTUNITIES (Polymer Research) SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES

Two posts of Research Assistant are available, one at a more senior level (starting salary £3,500) than the other (starting salary £2,940), for three-year studies of the behaviour of crosslinked polymers and related materials in host wet environments. Good honours graduates should contact the Academic Registry, Dept. AO, quoting reference NTL for details and application forms (to be returned as soon as possible) Kingston Polytechnic, Penrhyn Road Kingston upon Thames KT1 2EE. Tel. 01-549 1366. 2014(A)

# INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS (I.C.R.I.S.A.T.)

Hyderabad, India

needs the following personnel to work in West Africa.

## PLANT BREEDER (PEARL MILLET)

Responsible for planning and conducting research, in cooperation with a team of international scientists, to develop varieties and advanced breeding materials. Qualifications: Ph.D. in Plant Breeding with excellent academic record; at least five years' research experience in plant breeding, preferably of millet as evidenced by publications/reports, and in organisation and coordination of research. Knowledge of modern techniques in crop improvement and experience of semi-arid tropics would be advantageous. Bilingual ability in English and French preferred.

## SOIL AND WATER ENGINEER

Responsible for collection, analysis and interpretation of research information in management of natural resources and for evaluation of representative farming systems existing in the region. Qualifications: Doctorate with an excellent academic record in Soil and Water Engineering, Soil Physics, or Agricultural Engineering, with substantial formal training in hydrology; proven ability for teamwork with other scientists in interdisciplinary research programmes. Experience in agricultural research pertaining to less developed countries of the S.A.T., at least five years' postdoctoral research experience, and ability to speak and write French would be advantageous.

## AGRONOMIST

Responsible for devising and executing research programmes on cropping systems, soil fertility and soil management for pearl millet, groundnut, and other crops in the region, in consultation with a team of international scientists. The research will be aimed at developing systems of farming which increase and stabilise yields. Qualifications: Ph.D. in Agronomy or associated science; seven years' experience in agronomic research ability to lead a team of scientists in interdisciplinary research. Experience in agricultural research in less developed countries of the S.A.T., knowledge of I.C.R.I.S.A.T.'s Farming Systems Research, and fluency in French would be desirable.

Salary commensurate with qualifications; excellent fringe benefits.

Send resume by September 15, 1979 to: Director, I.C.R.I.S.A.T., 1-11-256, Begumpet, Hyderabad 500 016, India. W152(A)

# SOUTH GLAMORGAN HEALTH AUTHORITY (TEACHING)

## UNIVERSITY HOSPITAL OF WALES

Department of Haematology

## SCIENTIFIC OFFICER

There is a vacancy for a graduate in Mathematics to work as a Scientific Officer in the Department of Haematology in the University Hospital of Wales. This post would be suitable for a person wishing to apply their mathematical expertise to medicine within an active clinical and laboratory environment. In addition to routine duties relating to data processing and quality control, the successful applicant would be expected to take part in the research and development activities of the Department. The development of new mathematical applications within the field of Haematology would be encouraged.

The appointment will be at Scientific Officer level within the scale of £3,486 to £4,899 (under review)—Whitley Council Terms and Conditions of Service.

Further particulars may be obtained from:

Dr I. Cavill. Tel. (0222) 759444, Ext. 2365/2364.

Application forms from: Personnel Department, University Hospital of Wales, Heath Park, Cardiff. Tel. (0222) 755944, Ext. 2917.

Closing Date: June 22, 1979.

2047(A)

# M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital)

Watford Road, Harrow, Middlesex HA1 3UJ

DIVISION OF PERINATAL MEDICINE

## POSTDOCTORAL ENZYMOLOGIST

required to work on developmental enzymology in man with emphasis on mitochondrial systems. Previous experience in the biochemistry of mitochondria is therefore desirable. Further details are available from Dr R. A. Harkness, Division of Perinatal Medicine, Clinical Research Centre, Harrow HA1 3UJ, Middlesex. Tel: 01-864 5311, ext. 2712.

This appointment will be for three years only. Salary within the range £4,408 to £6,080 plus £502 London Allowance. Further details and application form from Mrs J. Tucker-Bull, quoting Reference 133/1/4267. Closing date: July 2. 2007(A)

# UNIVERSITY OF GLASGOW POSTDOCTORAL RESEARCH ASSISTANTSHIP DEPARTMENT OF BIOCHEMISTRY

Applications are invited for an M.R.C. funded Research Assistantship to be filled at postdoctoral level. The post is with a group studying the molecular biology of antibody formation with emphasis on the application of recombinant DNA technology. Experience in molecular immunology or recombinant DNA techniques is desirable, but a general background in nucleic acid biochemistry would be suitable.

Containment facilities (categories 1, 2 and 3) are available in the Department of Biochemistry and cloning of murine and human genes is in progress.

The position is available from July 1, 1979, and is funded for 5 years.

Salary will be within Range 1A of the salary scales for Research and Analogous Staff (£4,232 to £7,145, under review) with appointment at a point appropriate to age and experience.

Application with curriculum vitae and names of two referees should be sent as soon as possible to Professor R. A. Williamson, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 4464M. 2009(P)

# UNIVERSITY OF LIVERPOOL

DEPARTMENT OF  
BIOCHEMISTRY

## Applications are invited from ORGANIC CHEMISTS/ BIOCHEMISTS

for the post of Postdoctoral Senior Research Assistant to join a group working on the biosynthesis and metabolism of the ecdysteroids in insects and plants. Experience of steroid or terpenoid chemistry will be an advantage but not essential.

The appointment is tenable for a period up to two years and would start as soon as possible but preferably not later than October, 1979. Initial salary within the range £4,232 to £5,048 per annum (under review) plus U.S.S. Benefits.

Applications, together with the names of two referees, should be received as soon as possible by The Registrar, The University, P.O. Box 47, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/629/N. 2045(A)

# ASSISTANTSHIPS

## BRIGHTON POLYTECHNIC

FACULTY OF NATURAL AND  
LIFE SCIENCES

## RESEARCH ASSISTANTSHIPS

Vacancies exist in the following Departments:

APPLIED CHEMISTRY  
APPLIED PHYSICS  
PHARMACY

Salary scale: £2,613 by £87(2) to £2,787.

Details of posts and application forms from Administrative Officer, Faculty of Natural and Life Sciences, Brighton Polytechnic, Moulsecoomb, BRIGHTON BN2 4GJ, to whom completed forms should be returned by Friday, July 13. 2068(A)

# ASSISTANTSHIPS—cont.

## UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY JUNIOR

## RESEARCH ASSOCIATE

Applications are invited from Honours Graduates for the position of Junior Research Associate (Salary Scale 1B: £3,689 to £5,321) in the above department. This position, which is funded by a project grant from the Medical Research Council, is available from October 1, 1979, for a period of three years. It may be possible for the successful applicant to register for the degree of Ph.D.

The work will involve a study of the regulation of the hormone-sensitive triglyceride lipase from adipose tissue, and will utilise a wide variety of techniques of enzymology and protein chemistry.

Applications, including a curriculum vitae and the names of two referees, should be sent as soon as possible to Dr S. J. Yeaman, Department of Biochemistry, Ridley Building, University of Newcastle upon Tyne NE1 7RU. 2052(A)

## KINGSTON POLYTECHNIC SCHOOL OF GEOLOGY RESEARCH ASSISTANTSHIP

Research Assistant required from August 1979 to work on

THE BIOSTRATIGRAPHY AND  
GEOCHEMISTRY OF  
PHOSPHATE-RICH STRATA IN  
EUROPE AND NORTH AFRICA

Directed jointly by Drs R. T. J. Moody and I. F. Hazell. The selected candidate will be expected to register for a higher degree.

Salary range £2,940 to £3,114 inclusive.

Details and application forms (to be returned by June 29, 1979) quoting Ref. NT3, from Academic Registry, Dept. AO, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366. 2015(P)

# AWARDS

## UNIVERSITY OF NOTTINGHAM DEPARTMENT OF ZOOLOGY

Applications are invited for a

## C.A.S.E. AWARD

to work on the mechanisms of uptake of tickicides by the cattle tick (*Boophilus* sp.). Candidates should have a good honours degree in zoology and a special interest in physiology and cytology. The work which can lead to a higher degree will be carried out in the Zoology Department, Nottingham University and Boots Animal Research Centre, Thurgarton.

Applications should be addressed to the Department of Zoology, Nottingham University, closing date June 18, 1979. 2022(N)

# STUDENTSHIPS and FELLOWSHIPS

## GUY'S HOSPITAL MEDICAL SCHOOL (University of London) PHYSICS DEPARTMENT

## AN M.R.C. STUDENTSHIP

is offered for work leading to a Ph.D. in: the Non-Invasive Investigation of Cardiac/Vascular Disease using Doppler-Shift Ultrasound.

Candidates should possess or expect to achieve a 1st or 2nd Class Honours degree in Physics or a Life Science.

Apply in writing, with a brief curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, by June 15, 1979. 2006(F)

Continued on next page

## STUDENTSHIPS and FELLOWSHIPS continued

**UNIVERSITY OF EDINBURGH**  
**DEPARTMENT OF CHEMISTRY**
**S.R.C. C.A.S.E.****RESEARCH STUDENTSHIPS 1979**

Applications are invited for S.R.C. C.A.S.E. Research Studentships starting in October 1979 on the topics and with supervisors and companies listed below:

- Dipolar Cyclo Additions in Polymerisation  
Dr R. M. Paton/I.C.I. Organic Division
- Vinylchloride Precipitation Polymerisation  
Dr W. D. Cooper/I.C.I. Plastics Division
- Micro-columns for HPLC  
Professor J. H. Knox/I.C.I. Organics Division
- Catalytic Reactions of Hydrocarbons on Treated Aluminas  
Professor C. Kemball/I.C.I. Petrochemicals Division
- Mechanism of Dissolution of Organic Solutes by Water  
Dr B. M. Lowe/Unilever Research Ltd.

Applicants should hold or expect to hold at least an upper second class honours degree in chemistry or a related subject and should write, giving the names of two academic referees, as soon as possible to:

**Professor C. Kemball,**  
**Department of Chemistry,**  
**University of Edinburgh,**  
**West Mains Road,**  
**EDINBURGH EH9 3JJ**

2054(F)

**UNIVERSITY**  
**OF YORK**
**DEPARTMENT OF BIOLOGY**  
**S.R.C. C.A.S.E.**  
**STUDENTSHIP**

with Dr M. Davies, for three years from October 1, 1979, in collaboration with Simon-Hartley Ltd., Stoke-on-Trent. Enhanced efficiency in waste-water treatment is sought through studies of the physiology and biochemistry of growth in a novel completely mixed microbial film fermenter. The dependence of the population distribution on oxygen and substrate gradients within the biomass support particles is of fundamental interest.

Candidates should have or expect to obtain a first or upper second class honours degree in microbiology or biochemistry.

Apply to Dr M. Davies, Department of Biology, University of York, York YO1 5DD (telephone 0904 59861, ext. 5833), from whom further information may be obtained. 1091(F)

**UNIVERSITY OF**  
**SOUTHAMPTON**  
**DEPARTMENT OF**  
**ELECTRICAL ENGINEERING**  
**RESEARCH IN**  
**ELECTRICAL MACHINES**  
**TWO C.A.S.E.**  
**STUDENTSHIPS**

are available from October 1979. One of these is sponsored by G.E.C. Turbine Generators Limited, Stafford, and is concerned with magnetic field problems in large generators. The other is sponsored by the Central Electricity Research Laboratories, Leatherhead, and is concerned with electromagnetic problems in superconducting generators. Several weeks each year will be spent with these sponsors who will augment the basic S.R.C. grant by at least £550 plus expenses.

The successful candidates will be expected to register for a higher degree.

Applications, with curriculum vitae and the names of two referees to Mrs M. Campbell, Department of Electrical Engineering, The University, Southampton SO9 5NH. Please quote Ref. N. 2058(F)

**Royal Holloway College**  
**(University of London)**
**S.R.C. C.A.S.E. Studentships**

Applications are invited for two S.R.C. C.A.S.E. Studentships in the Department of Chemistry.

- (1) "C I mass spectrometry of synthetic base oils", with Dr R A Hancock and Burmah Castrol Company.
- (2) "Computer simulation of the interface between ionic crystals and solution", with Professor K Singer and Unilever Research Laboratory.

Applications, giving the names of two referees should be sent as soon as possible to the Registrar, (N) Royal Holloway College, Egham, Surrey, TW20 0EX. Further particulars may be obtained from the Department of Chemistry (Tel. Egham 5351). 2039(F)

**of higher education**

**KELSTERTON COLLEGE, CONNAH'S QUAY,**  
**DEESIDE, CLWYD**

**S.R.C. C.A.S.E.**  
**STUDENTSHIPS**

Applications are invited for two S.R.C. C.A.S.E. Studentships, tenable from 1st October, 1979 for work on the following projects:

1. "Mechanism of lipid oxidation in aqueous emulsions", in collaboration with Unigate Ltd. Supervisor: Dr J. C. Allen.
2. "Radioimmunoassay of polyamines", in collaboration with Ortho Diagnostics, Ltd. Supervisors: Drs J. C. Allen and C. J. Smith.

The co-operating bodies will supplement the SRC Studentships by £250 p.a. Applicants should possess or expect to obtain 1st or upper 2nd class Honours, and should write as soon as possible, with curriculum vitae, to the Institute Registrar, North East Wales Institute, Kelsterton College, Connah's Quay, Deeside, Clwyd CH5 4BR.

1061(F)

**UNIVERSITY OF YORK**  
**DEPARTMENT OF**  
**BIOLOGY**  
**S.R.C. C.A.S.E.**  
**STUDENTSHIP**

An S.R.C. C.A.S.E. Studentship is available for three years from October 1979 to work under the supervision of Dr A. W. Robards in collaboration with I.C.I. Plant Protection Ltd. (Jealott's Hill) on the effects of formulation adjuvants on plant cuticles. The work will involve a range of radiochemical, physiological and electron microscopical techniques with the aim of improving the uptake of foliar applied pesticides.

Candidates should have, or expect to obtain, a first or upper second class honours degree in a relevant biological subject.

Further information may be obtained from Dr A. W. Robards, Department of Biology, University of York, York YO1 5DD (tel. 0904 59861, ext. 5822).

2043(F)

**UNIVERSITY OF**  
**READING**  
**S.R.C. RESEARCH**  
**STUDENTSHIP**

Applications are invited from British or Commonwealth subjects for an S.R.C. Research Studentship tenable for 3 years in the Department of Microbiology from October 1, 1979. The successful applicant, who must have at least a Class 2 division 1 honours degree in Microbiology, Biochemistry or a related subject, will do research for a higher degree. Projects are available in microbial physiology and biochemistry, bacteriology, virology, serology, ecology and genetics and applicants should indicate their area of interest when applying.

The value of the award is £1,610 per annum tax-free (under review) with remission of approved fees.

Application form from Dr L. J. Zatman, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ. (Ref. M. 38A.) 2004(F)

**UNIVERSITY OF ABERDEEN**  
**DEPARTMENT OF**  
**OBSTETRICS AND GYNAECOLOGY**  
**M.R.C. POSTDOCTORAL**  
**RESEARCH FELLOWSHIP**

Applications are invited from suitably qualified biochemists to work as part of a clinical group, under Professor Klopfer, on isolation, assay and clinical application of new proteins isolated from the placenta.

Experience in immunological techniques and protein handling would be advantageous.

Appointment will be for 2 years, \* commence as soon as possible. Salary within Range 1A, £4,232 to £7,140 per annum (under review), with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by June 29, 1979. 2016(E)

**GUY'S HOSPITAL**  
**MEDICAL SCHOOL**  
**(University of London)**
**BIOCHEMISTRY AND**  
**CHEMISTRY DEPARTMENT**

Applications are invited for a

**RESEARCH STUDENTSHIP**

in Biochemistry, funded by the Muscular Dystrophy Group of Great Britain, to work with Dr D. C. Wat over three years, on biochemical changes in the human erythrocyte membrane in relation to neuromuscular disease.

Applicants should have a good honours degree and will be expected to register for a Ph.D.

Apply in writing, with curriculum vitae and the names of two referees to the Secretary, Guy's Hospital Medical School, London Bridge Street 9RT, quoting Ref. B.C.2. 2020(F)

**UNIVERSITY OF ABERDEEN**  
**DEPARTMENT OF BOTANY**

Applications are invited for S.R.C. C.A.S.E. Studentship for three years in Plant Pathology to work in the above department and at the Scottish Horticultural Research Institute, Dundee, commencing October 1, 1979. The project is to develop inoculation technique for *Elsino veneta* (a fungal pathogen of raspberry).

Application forms and further particulars from the Science Faculty Office, University of Aberdeen, Regent Walk, Old Aberdeen. (2031)J

**UNIVERSITY OF  
WARWICK  
RESEARCH FELLOWSHIP  
IN VIROLOGY**

Applications are invited for a Post-doctoral Fellowship in the Tumour Virus Research Group in the Department of Biological Sciences. The successful applicant will work in a small group studying the biochemistry of C type RNA tumour viruses, with particular reference to their ability to transform cells. Experience of nucleic acid technology and in particular the use of *in situ* hybridization techniques, while not essential, would be an advantage. Starting salary will be between points 1 and 6 on the Research 1A scale: £4,232 (£5,591) £7,145 per annum. The Fellowship (funded by the Medical Research Council) is available from October 1, 1979 and is renewable on an annual basis until September 1981. Further details and application forms from the Academic Registrar, University of Warwick, Coventry, CV4 7AL quoting Ref. No. 43/A/79. Closing date for receipt of applications is June 22, 1979. (2036)E

**UNIVERSITY OF  
EDINBURGH  
DEPARTMENT OF  
BIOCHEMISTRY  
POSTDOCTORAL  
RESEARCH FELLOWSHIP**

Applications are invited for the above post supported by the Medical Research Council and tenable for 18 months from October 1, 1979. The project will investigate the biological significance of cytochrome c methylation and the use of methylation as a means of studying protein: protein interactions. Some experience in protein chemistry or enzyme purification is desirable.

Starting salary in the range £4,232 to £5,048 per annum.

Further information may be obtained from Dr G. W. Pettigrew, Veterinary Unit, Department of Biochemistry, Royal (Dick) School of Veterinary Studies, Summerhall, Edinburgh EH9 1QH, to whom applications including the names of three referees should be sent before June 30, 1979. Please quote Reference 5067. 2012(E)

**THE UNIVERSITY OF  
MANCHESTER  
S.R.C. C.A.S.E.  
STUDENTSHIP**

Applications are invited for a three-year C.A.S.E. Studentship, starting October 1, 1979, in the Organic Section of the Department of Chemistry for research leading to the degrees of M.Sc. and Ph.D. under the supervision of Dr J. M. Bruce in collaboration with Dr J. Elks of Glaxo Research Ltd., Greenford, on the synthesis of anthracyclines and related compounds. Applicants should hold, or expect to hold, at least an upper second class honours degree in chemistry, or its equivalent.

Further details can be obtained from Dr J. M. Bruce, Department of Chemistry, The University, Manchester M13 9PL, to whom applications, with curriculum vitae and the names of two academic referees, should be sent as soon as possible. 1095(F)

**UNIVERSITY OF OXFORD  
PHYSICAL CHEMISTRY  
LABORATORY**

**Applications are invited for a  
C.A.S.E. STUDENTSHIP**

in collaboration with the Meteorological Office, Bracknell, for the study of atmospherically important energy transfer processes at low temperatures using pulsed laser techniques. The studentship is available from October 1979, and candidates should have, or expect to receive, a First or Upper Second Class Honours degree in Chemistry, Chemical Physics, or a related subject.

Applications, which should include details of academic experience, and the names of two referees, should be made as soon as possible to Dr C. J. S. M. Simpson, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ. 2063(F)

As a Pharma Research Institute, we are a subsidiary of the worldwide SANDOZ-Group. Our objective is the discovery of new approaches to the therapy and prophylaxis of infectious diseases.

Currently, we offer a

**POSTDOCTORAL FELLOWSHIP**

in our Department of Biochemistry. This opening is concerned with the investigations on drug metabolism and drug produced toxicity in isolated cells and organs.

Preference is given to graduated candidates possibly with experience in biochemistry or biophysics.

The successful candidate will find excellent working conditions in well equipped laboratories. The appointment will be for an initial two-year period with the possibility of an extension for one additional year. We offer an attractive salary. Travel expenses from and to the country of origin will be paid.

Please send application including curriculum vitae and credentials to

Dr N. Zacherl, Personnel Manager  
SANDOZ Forschungsinstitut,  
A-1235 Wien, Brunner Straße 59,  
Austria.

(W 146)E

**UNIVERSITY OF  
CAMBRIDGE  
DEPARTMENT OF  
PHARMACOLOGY  
M.R.C.**

**RESEARCH STUDENTSHIP**

Applications are invited for a 3-year studentship to commence in October 1979. Candidates should have, or expect to obtain this year, a good honours degree in Biochemistry, Biophysics, Pharmacology, Physiology, or related subjects. The successful candidate will be expected to register for a Ph.D. and pursue research into pharmacological aspects of insulin secretion and the molecular basis of hypoglycaemic drug action. The research methodology involved will be multidisciplinary.

Applications together with a curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr E. K. Matthews, University Reader in Pharmacology, Department of Pharmacology, University of Cambridge, Hills Road, Cambridge CB2 2QD. 2029(F)

**M.R.C.  
RESEARCH STUDENTSHIP  
DEPARTMENT OF  
HUMAN NUTRITION  
LONDON SCHOOL OF  
HYGIENE AND TROPICAL  
MEDICINE**

(University of London)

Applications are invited for a Research Studentship to join a group investigating the regulation of growth, protein synthesis and degradation in muscle. The work is taking place at the Clinical Nutrition and Metabolism Unit at St. Pancras Hospital.

Applicants should expect to gain a first or second class honours degree in Biochemistry, Physiology, or Nutrition, and should be able to start in October, 1979.

Applicants should send a curriculum vitae together with the names of two referees to Dr D. J. Millward, Clinical Nutrition and Metabolism Unit, 4 St. Pancras Way, London NW1, as soon as possible. 2057(F)

**THE UNIVERSITY OF  
SHEFFIELD  
Wolfson Unit of Plant Cell  
Biotechnology  
DEPARTMENT OF  
BIOCHEMISTRY  
S.R.C. C.A.S.E.  
STUDENTSHIP**

In conjunction with B.P. Ltd. to study the utilisation of waste carbohydrate sources by isolated plant cells grown in large scale bioreactors. Position open to men and women graduates in Biochemistry, Microbiology or Plant Biochemistry with a 1st or 2(i) degree. Tenable from October 1, 1979 under regulations governing S.R.C. C.A.S.E. awards. Supervisor, Dr M. W. Fowler, Sheffield; Mr E. Peel, B.P. Ltd. Applications to Dr M. W. Fowler, Unit Director, Wolfson Unit of Plant Cell Biotechnology, Department of Biochemistry, The University, Sheffield S10 2TN. Telephone 0742 78555. Quote ref: R 307/G. 2033(F)

**UNIVERSITY OF SUSSEX  
SCHOOL OF  
BIOLOGICAL SCIENCES  
RESEARCH COUNCIL  
STUDENTSHIPS  
IN DEVELOPMENTAL  
GENETICS**

Applications are invited for post-graduate studentships (to commence October 1979) for research on

- The genetics of early embryonic determination and imaginal disc morphogenesis in *Drosophila melanogaster* (with Dr J. R. S. Whittle), and
- Early detection of genetic and developmental lesions induced by transplacental exposure to toxic chemicals (with Professor R. J. Cole).

Applicants should write as soon as possible to either of the above at School of Biological Sciences, The University of Sussex, Falmer, Brighton, Sussex BN1 9QG. 2051(F)

**UNIVERSITY OF  
READING  
DEPARTMENT OF  
APPLIED STATISTICS  
S.R.C. RESEARCH  
STUDENTSHIPS**

Applications are invited: one is an S.R.C. C.A.S.E. Studentship, in collaboration with A.R.C. Letcombe Laboratory near Wantage, concerned with the development and testing of mathematical models of cell proliferation in relation to plant growth; the other is a straight S.R.C. Studentship and involves applications of probability or statistics in some agreed area.

Apply, quoting Ref. M. 39A, with curriculum vitae and the names of two referees to Professor R. N. Curnow, Department of Applied Statistics, University of Reading, Whiteknights, Reading RG6 2AH, from whom further particulars are available. 2005(F)

**UNIVERSITY COLLEGE  
CARDIFF  
DEPARTMENT OF GEOLOGY  
S.R.C. (C.A.S.E.)  
STUDENTSHIP**

for research, leading to the degree of Ph.D., into the development of a new analogue video comparison and measurement system for a wide variety of shape-analysis applications in the natural, physical and applied sciences, and in industry. The project is run jointly by the Geology Department and E.O.S. Electronics Ltd.

Applicants should possess or expect to gain a first or upper second class Honours Degree in electronics or a closely related subject. Experience in a natural science would be an advantage.

Applications should be made as soon as possible to the Head of Geology Department, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further details may be obtained. 2049(F)

# We deliver a lot more than nucleotides.

**We deliver performance:** Every lot is tested to verify its biological activity.

**We deliver quality:** Highest specific activity, based on an exclusive mass determination procedure developed at NEN.

**We deliver more often:** Numerous new lot dates have been added to our schedule. (See table below.)

**We deliver fast:** Now European customers can have Monday delivery of Friday's new lots.

Request our new  $^{32}\text{P}$  nucleotides schedule.

	Specific Activity at Shipment (Ci/mmol)	New Lots Prepared	Tested for Biological Activity	
ATP [ $\gamma$ - $^{32}\text{P}$ ]	>5500	2 weeks	Polynucleotide kinase*	
ATP [ $\gamma$ - $^{32}\text{P}$ ]	1000-3000	6x/mo.	Polynucleotide kinase	
dTTP [ $\alpha$ - $^{32}\text{P}$ ]	>300	2 weeks	"Nick" translation**	
dATP [ $\alpha$ - $^{32}\text{P}$ ]	>300	weekly	"Nick" translation	The labeling of calf thymus DNA is demonstrated to be >1x10 <sup>8</sup> dpm/ $\mu\text{g}$ with each lot.
dCTP [ $\alpha$ - $^{32}\text{P}$ ]	>300	weekly	"Nick" translation	
dGTP [ $\alpha$ - $^{32}\text{P}$ ]	>300	2 weeks	"Nick" translation	
dATP [ $\alpha$ - $^{32}\text{P}$ ]	~1000	4 weeks	"Nick" translation	The labeling of calf thymus DNA is demonstrated to be >3x10 <sup>8</sup> dpm/ $\mu\text{g}$ with each lot.
dCTP [ $\alpha$ - $^{32}\text{P}$ ]	~1000	4 weeks	"Nick" translation	
dGTP [ $\alpha$ - $^{32}\text{P}$ ]	~1000	4 weeks	"Nick" translation	
dTTP [ $\alpha$ - $^{32}\text{P}$ ]	~1000	4 weeks	"Nick" translation	

(Not for use in humans or clinical diagnosis.)

# Speed and Sensitivity with Style

7 SEP 1979

Using the latest technology to provide eye-catching design, solid-state heating for the horizontal analytical column and a high temperature reaction coil for fast colour development, the LKB 4400 Amino Acid Analyser is capable of performing fast analyses on small sample volumes at the picomole level. Indeed a complete protein hydrolysate analysis, including regeneration and equilibration is carried out in only 65 minutes. Physiological fluid analysis takes less than 4½ hours.

With its built-in 70 sample autoloader and optional data handling accessory, the 4400 Analyser can fully automate your chromatographic separation.

The new Barbican Centre is much more than one of the most modern conference centres in one of the world's most historic cities. It's an Arts Centre, too.

For example, the Royal Shakespeare Company will have its new permanent home in the Barbican. So will the London Symphony Orchestra. And the Guildhall School of Music and Drama. There will be a new Art Gallery – one of the biggest in London. Culture in plenty.

And as for commerce, all the great City of London institutions such as the Bank of England, the Stock Exchange, the money markets, insurance

companies – they're all within easy reach. And history is everywhere. The Tower of London. St. Paul's Cathedral. Guildhall. The Monument. The whole atmosphere of the City reflects a long and glorious history. But to get back to conference facilities. If you look at the captions below you'll find most of the details you need. But for fuller details, just contact our Conference Director. He'll be glad to help. With

completion in 1980, we're already taking bookings for 1981 and onwards. The Barbican Centre, 11 Cromwell Tower, The Barbican, London EC2Y 8DD England. Telephone: 01-638 4141.

## London's new Barbican Centre – surrounded by centuries of history, commerce and culture.

A display and exhibition area with a total of 88,000 square feet (8,100 square metres).

The Barbican Conference Hall comfortably seats 2,000 delegates.

A variety of lecture theatres, seminar and committee rooms to take anything from 5 to 275 delegates.

The Film Theatre – with all the most up-to-date audio visual equipment – seats 300 people.

The Barbican Theatre seats 1,150

All in all, the Barbican Centre is flexible enough to house any kind of conference you wish to plan. Try it and see.

# THE BARR & STROUD INTEGRATING MICRODENSITOMETER- DESIGNED TO REDUCE YOUR LABORATORY WORKLOAD

If you have a regular requirement for full quantitative cell information, it's worth checking out the Barr & Stroud GN5 Integrating Microdensitometer. With a scanning duration of only four seconds yet giving a 0.25 micron resolution, it brings speed and precision to cell preparation analysis.

The use of highest quality Leitz optics ensures reliability of results for even the smallest specimens. For histochemical and cytochemical studies, accuracy is better than  $\pm 1\%$  over an optical density range from less than 0.1 to greater than 2.5.

Area measurement, electronic masking and

narrowband illumination are just some of the other features which make this instrument a most attractive addition to your laboratory.

The GN5 Integrating Microdensitometer yields results with a speed and at a level of accuracy that far outstrips the standards that can be achieved by manual methods of study.

Designed in accordance with ergonomic principles, it's comfortable to work with too.

Start to reduce your laboratory workload by sending for full literature today. Use the journal reply system or, alternatively, contact us direct.

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to  $e^a$  if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- (i) only one reference number need be used if the reference is to several papers by identical authors.
- (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

# Cutting laser technology down to size

The world's first diode laser optical recording system, developed by Philips, is remarkable, not only for what it can do, but also for how it does it.

For in order to record and/or retrieve  $10^{10}$  bits of information on a pre-grooved, double-sided, 12-inch disk, a breakthrough in state-of-the-art optical recording technology was required. Which is precisely what we achieved.

The optical read/write head shown here is a miracle of micro-precision engineering. Employing an AlGaAs (Aluminium Gallium Arsenide) diode laser and associated semiconductor modulator, it produces sufficient pulsed light output to write, or 'burn', 1- $\mu$ m data pits into the disk's tellurium-based recording film. A 40-gram optical system, as well as electro-optics for tracking and focusing are also

# PHILIPS

contained within the ultra-compact head.

Light output from the laser is split by the optical system into two beams: 90 percent intensity for recording and 10 percent for reading. The read beam passes two mirrors and a beam splitter that are arranged to recombine the record and read beams at the objective, which focuses onto the information layer in the disk with an accuracy of  $1\text{-}\mu\text{m}$ .

And to complement the precision and compactness of the optical read/write head, equally ingenious radial tracking and error-detection correction systems had to be developed.

Diode laser optical recording is one example of Philips' ability to translate advanced technology into practical innovation. Here are some others.

CERN, the Geneva-based European Organisation for Nuclear Research, is to install four 500kW, 200MHz power amplifiers for their Super Proton Synchrotron, which is currently operating at a level of 400GeV. The new power amplifiers will provide additional RF power to double the Synchrotron's present capacity to facilitate experiments in high energy physics. Each of the four amplifiers employs 17 air-cooled coaxial power tetrode tubes of metal ceramic construction; power output per tube being approximately 37.5kW. The contract, awarded to Philips, calls for the supply and installation of the amplifiers as well as supply of spare tubes for a period of ten years.

**Fibre optics transmission.** Trials on a long haul fibre optics telephone transmission route, covering a distance of ninety-six kilometres, has been successfully completed at the Philips laboratories in the Netherlands. Essentially, the route comprises a 19mm diameter cable containing six 0.1mm fibres with a regeneration stage every eight kilometres.

**Tokyo Institute of Technology** has installed a Philips PW1100 computer-controlled Single-Crystal Diffractometer to assist in structure analysis of inorganic materials. One of Japan's leading universities, the Tokyo Institute of Technology, is noted for its academic research into the field of inorganic materials. And the new installation will be used by crystallographers from all over the country.

## Not the percentage but the cash

How much should a nation spend on research and development? Advanced industrial countries generally devote between one and two per cent of their gross domestic product to R & D; usually somewhat more than half of the figure will come from government sources, the rest from private investment. Recent OECD figures (*OECD Observer* No. 97) show that Britain, devoting 2.1% of its GDP to R & D, still seems satisfyingly committed to science and technology. The reality is somewhat different.

Britain's GDP is (on a per capita basis) little more than half that of many other industrial nations. So if we ask how much money per capita is spent on R & D, Britain's position looks decidedly less distinguished. Whilst the US spends \$200 per capita annually, Germany \$176, Sweden \$171, the Netherlands \$146, France \$130 and Japan \$103, Britain only manages \$92. Comparisons look even less happy when an allowance is made for defence R & D in which the United Kingdom is a heavier spender than almost any other nation. The conclusion has to be that in civil

R & D expenditure the UK is quietly losing touch with the rest of the industrialised world; not through any visible lack of enthusiasm for science and technology but simply through lack of resources.

Talks of cuts in public expenditure are very much in the air at present as a new Conservative government tries to live up to its election pledge of tax reductions. On the other hand, the Advisory Board for the Research Councils recently made a strong plea for 4% real growth in science expenditure in the coming years. The many government departments with significant commitment to R & D will find it easiest to go for a middle path—no real growth. But in another ten years our relative scientific position will then be much worse and scientists will be taking every opportunity to emigrate.

There is no guarantee that a stronger commitment to science and technology will boost the economy—but there hardly seems any doubt that support which is relatively weaker on an international basis will do permanent harm to the nation. □

## More on your fuel bill

THE winter in Britain is now over. Any further freak snow-storms, freezes, high winds and flooding should be attributed to next winter; this past winter, by general consensus a miserable one, cannot be blamed indefinitely. There is one final reckoning, however: the last quarter's gas and electricity bills sitting unwanted on doormats around the country.

These bills, everyone must know, are produced by computer. How else would we have a line reading 'VAT at 0% on £72.18=£0.00'—or a 52 digit code number sternly marked 'for machine use only'? But what is surprising is not what the computer does to embellish these straightforward demands for money—it is what it leaves out.

Every organisation devoted to the selling of energy is at least nominally also interested in conserving the stuff. Conservation, however, is not just a question of double-glazing and thick sweaters; it is, or at least it should be, yet another part of that monster of the 1970s—the information industry.

The most valuable piece of information that any energy consumer can have at present is how conservation measures have cut down fuel bills. Did recently installed insulation in the attic have any perceptible effect on the

use of fuel? If so, that little bit of information, passed round from person to person, is a much greater incentive to others to invest in conservation measures than is any advertisement proclaiming the merits of insulation. If on the other hand fuel is not conserved thereby, then the consumer should equally be alerted that all is not well.

Presumably within the computers of the utilities there is information on each consumer's energy usage over a period of many years. This by itself would not be adequate to allow for weather fluctuations. But someone, somewhere must be collecting rudimentary data on how cold it is—such as the simple but valuable 'degree-days' measure widely publicised in the United States. It is surely not beyond the wit of the energy utilities to provide a line on each bill giving, say, the number of units consumed per degree-day for the quarter in question—and corresponding figures for the past five years.

No doubt there can be endless discussion about the merits of various units, the possibility that consumers will misinterpret the figures, the fraction of fuel that is used for heating and so on. But anything would be better than today's total lack of information. And there is room on the bill—that line about  $0 \times £72.18 = 0$  could go for a start. □

# Problems with the shuttle cause concern for US space science programmes

David Dickson reports from Washington

TECHNICAL problems and the related cost over-runs of the National Aeronautics and Space Administration's space shuttle programme are raising serious concerns about the possible impact on planned space science missions. So far, no major changes in these missions have been necessary. But with performance margins being squeezed increasingly tightly, contingency plans are already being drawn up for two planetary missions that depend on space shuttle launches—one to send a pair of space vehicles to Jupiter, and the other to send two vehicles to the Sun—in case any further difficulties arise.

Equally important in the medium term is the effect the current shuttle problems could have on new space science programmes. At present Congress seems prepared to accept that the military need for the shuttle is sufficient to justify paying the increased costs recently announced by NASA; but whether it is also prepared to support new space programmes remains uncertain.

Senator Adlai Stevenson Jr., chairman of the Senate subcommittee on science and space, warned at a hearing of the subcommittee last week that the shuttle problems could require an extra \$500 million a year from the US taxpayer to maintain a civil space programme. "And that may prove to be too high a price to pay," he said.

The most direct manifestation of the shuttle's problems have been the delays caused by problems in engine testing and, more recently, in fixing the heat-protective tiles to the outer skin of the orbiter. NASA officials now admit that the shuttle is unlikely to be airborne before next spring, perhaps even as late as the summer: and Dr Robert Frosch, NASA administrator, told the Senate subcommittee that total cost overruns for the design, development, test and evaluation part of the programme were now expected to be about 15%—or roughly \$1 billion in current dollar values—compared to a 7% estimate last year.

The engine problems, however, have also had effects on the programme. For example the reduced performance estimates for early shuttle launches have led to erosion of engineering and weight margins in space science payload design. One programme to have been affected by this is Project Galileo, a twin probe and orbiter due to be launched from the shuttle in 1982, the former to provide the first direct samplings of the planet's atmosphere,

the latter to transmit data from an elliptical orbit through all regions around the planet, including at least 11 near encounters with its surface.

The complexities of the manoeuvring required of the two vehicles on reaching the planet have resulted in a slightly heavier design than first anticipated. Initial fears that this might require discarding some of the scientific experiments have now been circumvented; but the extra weight together with the reduced performance expected of the early space shuttle flights, have required significant design changes in the so-called Interim Upper Stage (IUS) which will launch the Galileo vehicles from the shuttle.

At present, assuming that the IUS development goes as planned, performance margins appear to be acceptable. "We seem to have got the weight problem under control, and the project itself looks in pretty good shape at the moment," project scientist Dr Torrence V. Johnson of the Jet Propulsion Laboratory in California said last week.

Any further problems, however, either in the IUS development or in the shuttle test schedule would be a serious matter. At present Galileo, which will be among the first operational shuttle launches, is planned for early 1982, to reach Jupiter in the middle of 1985. On this schedule the spacecraft would fly close to Mars,

using that planet's gravitational pull to help it on its way.

A major delay in the shuttle programme, however, pushing the Galileo launch into 1983, would mean that the gravitational pull of Mars could not be used. Extra fuel would then be required to get the spacecraft to Jupiter, and some of the scientific projects would be dropped to compensate for the extra weight.

Various contingency plans are already being studied by NASA. One possibility might be to split the mission into two halves, sending the orbiter and the probe separately, perhaps a year apart; but this would involve considerable extra cost, and a major redesign.

Another project similarly affected by weight considerations is the international solar polar mission (ISPM). This is a joint project between NASA and the European Space Agency, due for launch at the beginning of 1983, which will involve sending two spacecraft simultaneously past Jupiter and into opposing orbits over the poles of the sun. Some of the potential weight problems for this mission have been compensated for by changing the trajectory of the launch from the shuttle. But the margins are now very tight (technically the ISPM is now 70 pounds—or 5% overweight, compared to 146 pounds for Galileo); and any problems with the IUS could have severe consequences.

As a contingency plan, NASA has

Space shuttle: setbacks are keeping other projects firmly on the ground

suggested that the two vehicles might be launched separately, possibly up to a year apart. But ESA scientists are not very happy with this suggestion, pointing out that a simultaneous launch is one of the attractions of the mission.

Weight problems are also causing concern to planners for the first Spacelab flight. This is still scheduled to take place in August 1981, a date that ESA officials are confident can be met even with considerable slippage in the shuttle test programme.

However as things stand at present, the shuttle may not be ready to provide enough thrust by this stage to launch the full Spacelab payload. The current shortage is about 1,300 pounds out of a total weight of about 65,000 pounds; and it could mean that some of the experiments already lined up for the first Spacelab flight may have to be dropped. (One encouraging piece of news to ESA officials is that the US Air Force appears to be planning to use Spacelab for some of its own manned space-flight missions.)

The space shuttle problems are already affecting other areas of NASA's activity. Scientists involved in the Voyager mission, for example, feel that if it had not been for these problems, they might have had access to some extra money this summer for additional experiments.

The greatest uncertainty at present, however, is over what the political effects of the shuttle's problems will be on support for future projects. NASA, with the support of both the Office of Science and Technology Policy and the Office of Management and Budget, is adamant that none of the existing programmes should be cut to provide the additional funds needed by the shuttle.

Dr Frosch told the Senate subcommittee that cancelling the Galileo project—at one time discussed as a distinct possibility—would only save \$83 million in 1980, considerably less than the extra money needed by the shuttle; nor would much be gained by taking money from the space telescope. "We do not consider either of these reasonable ways of getting extra funds," he said.

But the concern is that Congress, having provided NASA with the extra shuttle costs largely on the grounds that the success of the programme is required for US Defense plans—in particular for launching surveillance satellites, will be reluctant to complement this with support for new space science missions.

The situation is already bleak following the decision of the Carter administration not to request any new starts for the fiscal year 1980 partly to ensure adequate support for space

shuttle. (Among projects which NASA had submitted to OMB were plans for a shuttle-launched gamma-ray observatory, an orbiting imaging radar to Venus, and a mission to the comets Halley and Enke.)

"The real question is going to be what the 1981 budget contains. A second year with no new starts could really put the science programmes in jeopardy; if the nation wants a vigorous space science programme, then you have to start something new," Professor A. Cameron of Harvard College Observatory, chairman of the National Academy of Science's space science board, said last week.

Of course, if there are no new starts in the 1981 budget request the fault will not lie entirely with space shuttle; equally important may well turn out to be President Carter's desire to greet an election year with an attempt at a balanced budget.

But the additional funding which NASA is currently seeking from Congress for 1980 (\$225 million above its original request), has not improved the situation. "We are still hopeful that our project will be funded, but we are not as optimistic as we were a month ago," says one of the scientists involved with the gamma-ray telescope, currently top of the NASA's space astronomy and astrophysics board's priority list for future projects.

The dangers in the current situation have not been lost to Senator Stevenson who, with fellow committee member and ex-astronaut Harrison (Jack) Schmitt, has been urging a more aggressive space programme on the administration for some time.

"The problem with the shuttle programme now seems to have been a serious underfunding in the early stages, something of which up to six weeks ago the Congress had been unaware. And now it has all come home to roost with a 15% cost over-run," Mr Stevenson said at the subcommittee hearing last week.

"The biggest cost may effectively be the end of the civilian space programme, since the real risk is that the price of the shuttle's difficulties will be taken out of the civilian side of our space efforts. And with the country in its present mood, this could well happen."

Not all observers are quite so pessimistic. But the problems raised for future space science funding are already being taken seriously, not only by NASA but also by both OSTP and OMB. And they will provide an unwelcome house-warming present to greet NASA's new associate administrator for space science, Dr Thomas Mutch, when he takes up his appointment next month. □

## California plans to build world's largest telescope

THE University of California is in the midst of preparing preliminary designs for a 10-metre diameter optical telescope that planners hope will be operating in the mid-1980s. Two designs are being considered, each a radical departure from conventional optical telescopes, which would be prohibitively expensive to scale up to this size.

The proposed telescope would be by far the largest in the world, with a mirror twice the diameter of the Hale telescope on Mount Palomar. (Nominally the largest telescope in the world is now the 6m at Zelenchukskaya Astrophysical Observatory in the Soviet Union, but western astronomers generally comment that it has not yet been proved reliable.)

Jerry Nelson, of Lawrence Berkeley Laboratory and chairman of the technical design committee for the proposed telescope told a meeting of Californian science writers last month that it would be designed to produce images smaller than 0.5 arc seconds and that, for good infrared observations, it would have to be built at a site with low atmospheric moisture.

Historically, the costs of optical telescopes with thick, monolithic glass mirrors have risen roughly as the cube of the diameter. This means that a conventionally designed 10-metre instrument would cost around \$200 million—a figure Nelson says is "out of the question". On the other hand, the design committee has already rejected such alternatives as the use of independently focused multiple mirrors, like the recently opened telescope at Mount Hopkins (*Nature*, 3 May, page 9). Such multiple mirror devices may provide an economical alternative for studying point sources, but the new University of California telescope must have angular field wide enough to encompass an extended image like a galaxy with associated star clusters.

Nelson's design committee has thus narrowed the acceptable options down to two: a single mirror much thinner than those used previously, or a segmented mirror with focusing characteristics approximating those of the monolithic design. In either case the anticipated principal focal length would be between 15 and 20 metres, which would facilitate a relatively small containment structure. Traditionally half the expense of building a new observatory has gone into the telescope and half into the surrounding structure, so every effort is being taken to minimise the overall size.

The instrument will also be made more compact by the use of an altazimuth mount. Most large telescopes have been mounted with their axis of rotation parallel to that of the Earth, so that only one sweeping movement is required to track an object across the sky, but this so-called equatorial mount is relatively bulky. The advent of computer control has now removed the obstacles that once prevented use of the smaller but more complex altazimuth mount, which requires coordinated rotation about both the vertical and horizontal axes.

For either the thin continuous mirror or the segmented mirror, the question of how to evenly distribute the weight of the glass raises a host of unsolved problems. In either case 'active optics' will be required—that is, the stress on various support points must change continuously to prevent deformation of the glass when the mirror is tilted. The thin monolithic mirror would require some 100 to 200 support points, the majority of which must be active. On the other design, each segment of the composite mirror would require 12 sensors and 3 actuators to change its tilt and focus. On this point, at least, Nelson seems confident. "We think control is no problem," he says. A simple actuator device for segments of the composite mirror has already been tested and shown to be many times more precise than required, and the overall control scheme has been successfully modelled on a computer.

Preparing the glass, however, is another matter. A leading glass company has agreed to prepare the monolithic blank if that design is finally chosen, but many problems would remain in caring for the world's largest piece of fragile glassware. Among other things, the whole mirror, planned to be only 15 centimetres thick,

Possible segmented design for 10m mirror

would have to be enclosed in a vacuum tank each year for re-aluminizing. The segmented mirror also under consideration would require nine basic segment shapes to produce an overall parabolic curvature. The polishing might be done by computer control on segments already prepared for mounting, or possibly by a cheaper method—which Nelson calls "extremely promising"—in which the pre-stressed segments are polished spherically then released to snap back into the shape of an off-axis parabola. The ten centimetre thick segments would be hexagonal, 0.7 metres on a side, and mounted in three rings around a larger central mirror. The completed composite mirror would contain 54 segments.

The final cost should be in the range of \$20-50 million, of which the university hopes to raise at least half initially and then try to obtain matching federal funds. If construction can begin by 1981 the new telescope might be completed by 1986.

To avoid as much water vapour as possible, three relatively arid mountains have been proposed as possible sites. Mauna Kea, a 14,000 foot volcano in

Hawaii, would be the most accessible since the roads already lead to existing observatories on its peak. White Mountain in California, also 14,000 feet high, would be closer to the university's campuses, but the summit is almost unreachable by land vehicle. Junipero Serra Mountain is close to the UC Santa Cruz campus, which has a particularly active astronomy department, but with a height of only 6,000 feet it is by far the most moist of the three locations. Wherever the new observatory is built, the planners have already resigned themselves to building a structure sturdy enough to allow observations in the midst of 50 mph winds.

Nelson and others involved in the project sound optimistic about being able to build their proposed observatory, despite its high cost and necessarily radical design. They point out four broad classes of observation that would be facilitated by the proposed instrument:

- With direct optical imaging, a 10-metre telescope would permit better study of distant galaxies and a further attack on the problem of whether the universe will expand for ever or eventually collapse.
- Direct infrared observations would be used to study protostars and the structure of the galactic centre—perhaps resolving the question of whether it contains a massive black hole.
- Optical spectroscopy using the new instrument would allow astronomers to study globular clusters around other galaxies and investigate why quasars have absorption lines.
- Finally, infrared spectroscopy could be used to determine the abundances of various molecules in stars, and to study the emission spectra of quasars.

John Douglas

## Sussex students step up science exam protest

PROTEST escalated last week at the campus of Sussex University against a compulsory first-year preliminary science examination. Two students, Richard Flint, president of the student union and Shaun Fensom, an engineering student, were "excluded permanently" from campus by vice-Chancellor Sir Denys Wilkinson for their "leadership" of a student-union-mandated disruption of a resitting of the contested examination.

An emergency Senate meeting has been called for 13 June when the Vice-Chancellor will explain his action to the faculty.

Half the university's 4,000 students attended an emergency meeting on 5 June. They rejected a call for an

immediate occupation of university buildings, but voted to canvass university and staff to protest against the expulsion and seek support from campus trade unions. They also decided on a series of one-day strikes the first of which was held last Friday with mass picketing at university entrances. The vice-chancellor was turned away. Students estimated that attendance was reduced to 10%-20% of normal but administration officials claimed that the action had not achieved its aim of stopping all classes.

The protest is taking a form not familiar since the 1960s. The original campaign began two years ago when the student union voted for direct student action to end a compulsory

first-year examination in science subjects. The science division is the only one at Sussex with such a requirement. Arguing that the exam distorted teaching practices and served no useful assessment purpose, the union called for a boycott. In the first year the boycott was 65% effective.

In the meantime a nine-member faculty working party was set up to consider the students' demand. It rejected the students' proposal that the exam be made optional, citing a need for "rigorous training in discipline", "an ability to marshal facts under pressure and to meet deadlines" and the "necessity for an objective means to monitor progress" as reasons for its decision. The working party specifically

rejected the students' request for tutorial assessment.

Students maintained their position, arguing that skill at examinations is unrelated to the skills it takes to be a competent scientist and that gearing the course towards quantitative assessment actually reduced learning. In January, a second boycott was called, with the addition that any

resitting of the exam that included boycotters would be disrupted.

The second boycott was far less successful with only 10% of the students failing to attend. Nevertheless the university rescheduled the exam to include students who had participated in the boycott. The exam was disrupted by 25 students who occupied the room. A second resitting was re-

scheduled, this time with faculty, police and photographers in attendance, but the students banged on tin cans and drums outside the examination room.

On 1 June, the two students were summoned to the vice-chancellor's office and expelled for their part in the disturbances.

## Soviets get their fun from learning about science

SOVIET society is in many ways surprisingly Victorian—a trend shown in the great popularity of the scientific lecture as a form of cultural entertainment. The organisation of such lectures is the task of the *Znanie* (Knowledge) Society, founded in 1947, which, in Soviet society, plays roughly the role of the British Association for the Advancement of Science, the Royal Institution, and the Worker's Educational Association in the United Kingdom.

Recently, two notable representatives of *Znanie*, Nobel Laureate Academician Basov and Dr Vladislavlev, toured the UK as part of the "Days of Soviet Science and Technology" organised in connection with the Soviet Exhibition at Earls Court. A delegation of 11 scientists and some 10 support personnel took part in the "Days". The host was the British Association—although, by some failure in communication, they were not aware until the delegation arrived of the great significance which Soviet science publicity puts on the organisation of such "Days". Nevertheless, one outcome of the visit was agreement to exchange lecturers between *Znanie* and the British Association—although it seems unlikely that the Soviet public will have the direct benefit of words of wisdom from the BA in the foreseeable future.

For *Znanie*, although lauded in official handbooks as being built on "democratic principles", is a hierarchical organisation. Although the society is supposed to organise lectures for any Soviet collective farm, factory or club that demands them, it would be impractical for top-flight lecturers to be constantly commuting, say, between Moscow and Vladivostok. "What we do", explained Vladislavlev "is to organise 'lectures for lecturers' in such remote places. Then the lecturers we have trained can give lectures at the local level".

If a top specialist is required, then the organisation requesting him must pay his fare. This suggests that the remote areas are somewhat dis-

advantaged—an idea which the visitors resolutely denied. As far as the Virgin Lands, and the far north of Siberia are concerned, they explained, there are special funds—and for the rest, there are no problems. Local lecturers are well trained to do their job in popularising science.

Lecturers, in fact, form the only 'members' of *Znanie* (apart from administration personnel). The main privilege of membership is to give frequent lectures (usually gratis) to whatever audience demands your services, and to attend frequent seminars on the latest developments in your field and the newest methods of lecturing. "The main problem", Vladislavlev explained, "is to make lectures appropriate for different audiences. That is why it is obligatory, when you ask for a lecturer, to describe the intended audience."

Not all lectures are simply a cultural diversion. *Znanie* is also responsible for the 'People's Universities', a fairly new feature of Soviet life. Courses are organised by plants and ministries to provide workers with the means of improving their professional qualifications.

*Znanie* itself is only concerned with the academic side—it is up to the factory commissioning its services to provide the facilities and to organise funding. Some 60% of *Znanie* funds, he added, come from non-state sources—factories, and trade unions. Of course, if a worker simply want to study, say, English Literature, he added, "then he pays for himself, just as if he was going to the cinema!"

To the Soviet mind, 'science' implies, as Academician Basov put it, "all advances in knowledge". Thus the 'flow-diagram' of *Znanie's* work includes 'Houses of atheism' in parallel with its planetaria. The most popular lectures organised by the society, according to Vladislavlev, are those on international affairs, followed by medicine.

Only the lecturers and organisers, not the audiences, are members of *Znanie*. If, say, some Ukrainian collec-

tive-farm wants to start a 'Bird-watchers' club', *Znanie* will provide lecturers and suggest reading matter, but the club cannot become an associate member of *Znanie*. Only high-level professional societies, such as the "Popov Radio-technical Society" has that privilege. (Some 40 such societies at present are 'collective members' of *Znanie*.)

Even so, with more than three million active members (lecturers and paid local organisers), there is no need to invite further people to join. "We have too many members already", Basov said. Some prominent personalities, of course, are virtually *ex officio* members. All Soviet cosmonauts, said Vladislavlev, are exploited enormously. "In fact, their bosses are always telling us to leave them in peace to get on with their job."

"There is an increasing demand for scientific knowledge and an increasing interest" said Vladislavlev. "The more one knows, the more one wants to know." As for the social impact of science, Academician Basov reiterated an earlier communication to the British Association that "science is not always good!" It would appear, however, that, in spite of a vast quantity of general science reporting (all major discoveries are reported in *Pravda*, Basov said), the Soviet public have not developed a "doomwatch outlook".

"It is *not* disasters that interest the public in science", said Vladislavlev, referring to Harrisburg. "The interest comes naturally from the rising cultural level."

And, as far as the Soviet citizen is concerned, everything is done to encourage that rise. "First we offer him a single lecture", said Vladislavlev. "Then, having caught his interest, a course of lectures. And finally, enrolment in a People's University. We are concerned in what you would call continuous adult education, and its development is our main task for the future!"

Vera Rich

## news in brief

**MRC staff committee prepares for budget fight:** Responding to a leak in *The Observer* (3 June) predicting extensive cuts in UK science in this week's budget, the Medical Research Council Staff Side Committee initiated actions last week to try to prevent the cuts. Petitions and telegrams from every MRC unit have been sent to Neil Macfarlane, Minister of Science, protesting cutbacks in research funding. Eight of the nine trade unions represented on the staff committee supported a move for an immediate meeting with Macfarlane but the minister refused the request calling it "premature". Staff side initiatives to make joint representations to the government with MRC management were similarly rebuffed last week. In a letter, MRC management rejected the possibility of joint action opposing budget cuts saying that management and staff should act independently since the two have different views. The full staff side committee will meet 20 June to make its long term plans to prevent damage to medical research in the UK.

**US scientists report successful laser fusion tests:** Scientists at the University of Rochester in New York suggested last week that the highly successful results of a series of experiments on a laser fusion energy system might bring forward the date at which break-even in fusion energy—the point at which the energy produced by the system equals the energy inserted—can be achieved.

The experiments were carried out using a six-beam ZETA laser system, the first stage of a 24-beam system scheduled to begin operation later in the year. Using a laser power level of  $1.65 \times 10^{12}$  watts, the experiment generated more than one thousand million neutrons, at temperatures of 67 million degrees. "This is between five and ten times the amount that was expected," Dr Moshe Lubin, director of the university's Laser Energetics Laboratory, said last week.

When the full 24-beam system is in operation, it is hoped to be able to produce 30 to 40 terawatts ( $\text{watts} \times 10^{12}$ ) of power. "The success of our first experiments means that it may be possible for us here at the Laser Energetics Laboratory to help the national programme move up the date that is projected for breakeven. That event is presently estimated to occur in the 1984 timeframe," said Dr Lubin.

**Third World energy experts to confront the West:** A symposium to be held in London 20–22 June will provide a forum for 30 spokespersons from the Third World to confront "the dominance being exercised by developed countries in science and technology, monetary expenditure, and planning and policy." The conference, titled Third World Energy Strategies and the Role of the Industrialised Countries is being organised by Ariane van Buren and Gerald Foley of the International Institute for Energy Development and is designed to give experts from the Third World a chance to address influential figures from western aid agencies and development banks in the areas of nuclear power, the role of multinational oil companies in development and the desirability of the alternate technologies currently in western vogue as being "appropriate" for the Third World. Papers will be pre-circulated and speakers will be restricted to five minute presentations thus allowing for up to one hour of debate. The papers and debates will be published. Sponsors of the meeting include the UK Ministry of Overseas Development, Atlantic Richfield, and the Beiger Institute of the Swedish Academy of Sciences.

**UNCTAD bodes ill for UNCSTD:** The increasing economic crisis facing the developed capitalist countries has produced a complete deadlock at the fifth UN Conference on Trade and Development. Four weeks of negotiations at Manila among 5,000 delegates from the world's rich and poor nations costing an estimated £100m have failed to reach agreement on any restructuring of the western world's economy. "The resolutions passed commit us to absolutely nothing" said one western delegate. Third World countries attempted to change current practices of the International Monetary Fund, to install a system of trade preferences and multilateral trade negotiations for developing countries and to break the industrialised nation's monopoly on shipping. Final resolutions condemned protectionism in trade against Third World products, provided for short and long term "action programmes" and expressed a need to progress towards an aid target of 0.7% of GNP. But several countries, including the UK, said they could make no commitment due to current cutbacks in public spending. The failure of the rich nations to yield to Third World demands for economic change reduces the possibility for effective action to be taken at the UN Conference on Science, Technology and Development to be held in Vienna in August.

**India extends ban on wildlife export:** The Union Ministry of Commerce has restricted wildlife exports to only 21 live species of birds, one live species of animal and products of six other animals, on the recommendation of a sub-committee of the Indian Board for Wildlife which examined the existing export policy from an ecological viewpoint. The only animal species that can now be exported is the striped squirrel; allowed bird species include myna (other than hill myna), parakeet, and two Himalayan species known for their colourful plumage—Sibia and Siva. Among the allowed animal products are the skins of common fox, hill fox, jackal and jungle cats, and peacock feathers and porcupine quills. The new policy follows an import-export order of January 1978 which banned most of the wildlife in demand abroad, and the recent revision will further hit the trade. The bird trade is worth 80 million rupees annually, the major portion being export: according to a recent report of the Royal Society for Protection of Birds, 4.5 million birds used to be exported from India every year. Export of munias, constituting 70% of the total bird trade, was banned last year, and the ban on the export of rhesus monkey (about 20,000 annually) and on the lucrative trade of pelts and furs of cat family and skins of lizards have drastically affected the animal trade. But there has been a concurrent increase in poaching and smuggling of wildlife and their products. Recently a global racket involving the

exchange of wrist watches and other luxury items for snake skins was uncovered in Bombay. So although conservationists and naturalists are pleased by the recent directive—except for jackal skin, an animal fast decreasing in number—they feel much more rigorous policing is required.

from Dilip M. Salwi,  
New Delhi.

"Keep your part of the bargain.  
Throw out the wrist watches!"

# Commercial break for Britain's science?

THE word 'atmosphere' liberally peppers the speech of Neil Macfarlane. It is used constantly in attempts to describe just how important good morale is for the country's scientific community, and in particular, the newly-appointed Minister for Science believes there must be infinitely better links between "the research atmosphere" of the good universities and industry in Britain.

"We have lost a lot of ground over the past 20 years now", he states. "Too many industrial organisations have turned to their companies' research activities when looking for savings on their annual budget." To rectify matters, he maintains that we must encourage companies to set up centres close to universities—as the Americans do. Similarly our universities must be more commercially minded in looking for closer ties with major firms.

But 43-year-old Mr Macfarlane stresses that the real effort must come from industry, which in the past has shown little regard for scientific and engineering talent. "I think it is greatly to be regretted that the engineer and the scientist are generally relegated to a secondary level in the hierarchy of any major industrial organisation in the UK. We have been taken over by financiers and lawyers."

These are candid words from a junior minister who has no scientific training and whose background is solidly commercial. Educated at Bancroft's School, Woodford Green, he was commissioned in the Essex Regiment from 1955 to 1957. He left "after Suez, the Middle East and all that particular cauffle" for the oil industry, to eventually become a sales manager with BP; he was closely involved in the 1973 oil crisis, dealing with the distribution of petrol in Southern England.

In February 1974, he was elected Conservative MP for Sutton and Cheam and straightaway sat on the Select Committee for Science and Technology. His experience there opened up a completely new interest in science and Mr Macfarlane is quick to defend the committee's record for giving a good overview of science and technology and for its many short, sharp investigations: "I think the whole atmosphere which then developed because of the decline of our industry prompted many of us to pursue various technological issues with vigour and at all levels."

He is certainly no supporter of the proposal by the Select Committee on Procedure for the dissolution of the science and technology group. "I

Neil Macfarlane (above), Minister for Science in the new Tory government, wants closer ties between industry and research

Profile by Robin McKie

would be very apprehensive if it was entirely disbanded because I would envisage a tremendous amount of duplication of its work by other government departments." But defenders of the committee cannot look to him as an ally in their fight for its retention, because he maintains that, as a member of the government, he has no right to intervene in a purely House of Commons matter.

Even if the committee is disbanded, Mr Macfarlane will remain optimistic, believing that in general both parliament and government serve science well. "I just wish that we could have a little more motivation of other Members of Parliament towards the importance of science. There is not nearly the interest that there should be." He believes the previous Labour administration did not help by giving all responsibility for science to the Secretary of State for Education and Science, Mrs Shirley Williams, without delegating to a junior minister. Education became such a political football that it took up most of her time, at the expense of science.

"However, I am not going to

criticise her all the way because I think in many respects she did show a tremendous interest and grasp, and doubtless she would have liked to have spent more time on science. But now there is someone who can spare that time and has access straight through to the Secretary of State who is totally involved himself. We have got to ensure that the science fraternity knows it is not neglected by this administration."

This desire is reflected in the breadth of Mr Macfarlane's role, which covers science, research, technology, engineering and preparing for the advent of the microprocessor revolution. Although there have been junior ministers for science before, they have not been faced with the same sweep of responsibilities.

One major problem is staff stagnation at university science departments, which is freezing promotions, preventing staff exchanges between centres and hindering the cross-fertilisation of ideas. Mr Macfarlane refuses to be pessimistic, however. "I don't entirely take a gloomy view of staff stagnation. It was probably bad eight or 10 years ago, maybe even four or five but I believe there has been a great awakening over this problem in recent years. Things are beginning to move and there is this exchange and cross-fertilisation taking place. We have just got to accelerate it somehow."

In general, he foresees "a period of stabilisation" for universities, with the emphasis being placed on training the 16-19 age group to provide skilled technician manpower for our industrial re-birth. The research councils can expect to continue with the level of funding which has occurred in the past couple of years.

On the thorny question of lay and union representation on the laboratory safety committees the Dangerous Pathogens Advisory Group and the Genetic Manipulation Advisory Group, Mr Macfarlane takes the same steadfast line as his Secretary of State, Mr Mark Carlisle, in opposing such moves. "These two bodies are so highly specialised that I don't believe there is a role for anybody else on them at this embryonic stage of their activities."

The real problem is using science properly in our industrial growth. "The main thing at the moment is that the atmosphere is right in the science departments—whereas five to 10 years ago it was very different. What I want to do is make Britain proud of its science, and that is going to be quite easy because our science is second to none. It is the very best." □

# How French 'postdocs' are left out in the cold

UNIVERSITIES have stopped growing in France, as in other western countries, and young scientists who want to make careers in research are feeling the pinch as badly as anywhere else. One paradox of this situation is that, at a time when postdoctoral fellowships are becoming scarce, researchers are increasingly reluctant to accept temporary posts, and less willing to change jobs merely to continue in research. While the problem is international, its French version has some special idiosyncracies.

Research in France is not as university-based as in some other western countries. A major role is played by the Centre National de la Recherche Scientifique (CNRS), which despite its name is not a place but an institution, financing a large number of research laboratories throughout France. Some of these are located on university campuses and some in the Grandes Ecoles, while others are free-standing. A fairly close analogy would be with the MRC research units in Britain.

Purely academic research is financed partly through the Ministry of Education and partly through the Delegation Générale à la Recherche Scientifique et Technologique (DGRST), a body which fulfils some of the functions of the UK Science Research Council. The DGRST provides a limited amount of finance for hardware, a fairly generous supply of research studentships, but only a very sparse ration of postdoctoral fellowships, a function which largely rests with CNRS. But CNRS does not provide fellowships for academic departments, only for its own laboratories and those 'associated' with it (which together accounted for some 7,600 research workers and 13,400 technicians in 1977). Since it is becoming steadily more difficult for university professors to raise funds for postdoctoral workers, as described later, there is a risk of prolonged contraction of academic research as compared with the CNRS-supported laboratories. DGRST is not now, it seems, in a position extensively to support either university research or that in the Grandes Ecoles, in the way SRC does in Britain by means of research grants (which often include funds for graduate research assistants), research fellowships, advanced fellowships and the like.

In France, all academics with teaching posts, and also employees of bodies like CNRS, are *ipso facto* civil servants (*fonctionnaires*) and as such have permanent tenure. They do not need therefore, and indeed are not entitled, to take part in the state's unemployment insurance scheme, ASSEDIC.

ASSEDIC was designed to cater for workers in private industry or commerce; it has been the subject of much negotiation between government and unions, and its terms were most recently improved last March. It is now a thoroughly comprehensive scheme—with one yawning omission: it does not cover temporary research workers ('postdocs') in universities, Ecoles, CNRS laboratories or similar establishments. French law is quite firm about this: postdocs are neither *fonctionnaires* nor are they employees in private industry, and so they slip neatly between the available stools.

French postdocs were not particularly concerned about this state of affairs until 1971 or 1972, when scientific unemployment first became noticeable. Pressure then began to be exerted on behalf of the postdocs by their

6

**An unfortunate quirk of French law, probably dating back to the Napoleonic concept of university, provides no proper legal status . . .**

9

trade unions, such as the Syndicat National de Chercheurs Scientifiques, for temporary research workers to be eligible for unemployment insurance. This was not conceded by the government, but a number of temporary postdocs were converted into a hybrid species, *fonctionnaires hors statut* (literally, civil servants outside the law), and as such attained tenure. DGRST found itself obliged to meet the cost of these new *fonctionnaires* and this limited its resources for maintaining posts for those who were still temporary, let alone creating new posts. For this reason, among others, scientific unemployment grew further. The unions became very restive and successfully prevailed upon DGRST to terminate its long established *contrats de recherche* (broadly similar to SRC research grants) which often incorporated money to pay for postdocs. The main aim was to force government agencies to make all research posts permanent, but the government has done the opposite. It has reduced the number of temporary posts without increasing the number of permanent positions.

Before this happened, industrial concerns had been in the habit of supporting contract research in universities, and financed a number of academic postdocs; but anxiety among young scientists facing the possibility of eventual unemployment without

state unemployment relief as well as union hostility, caused the withdrawal of industrial contracts, and these do not now appear to be a significant source of funds.

An unfortunate quirk of French law, probably dating back to the Napoleonic concept of the university, which provides no proper legal status and thus no insurance for those who are neither civil servants, self-employed nor employees of firms in the private sector, thus has seriously added to the plight of untenured French research workers. Initiatives to set up an unemployment scheme independent of the state do not appear, up to the present, to have met with success.

DGRST, aided by the new science minister, has striven valiantly to fill the gap left by the atrophy of contract research. In addition to some 3,000 2-year studentships for predoctoral students, and some 60 fellowships for tenured academics to enable them to devote some years to fulltime research, DGRST has now begun to provide postdoctoral fellowships available for allocation in the principal research laboratories. But at the time of writing the number available through DGRST is only of the order of 100, which falls a long way short of meeting the need. The greatest hardship is among newly graduated PhD's.

An influential working group of academics, industrialists and administrators presided over by Professor Jacques Friedel has been taking steps to assemble funds for some university fellowships, which have begun to be available at Orsay, Marseille, Strasbourg, Poitiers and Lille; other fellowships have been established in the State laboratories at Saclay and Grenoble. The insurance deadlock has not been resolved, but at least the decay of contracts is beginning to be circumvented.

This situation is however exacerbated by another specifically French problem, the firmly established tradition of young scientists to remain in the department where they researched their theses. Several administrators expressed the view to the author that the difficulty in persuading young scientists to move to other laboratories or to neighbouring disciplines, is the greatest single obstacle, after the insurance laws, to fuller scientific employment; and from a purely scientific standpoint, immobility has the grave disadvantage that the inflow of new ideas and experience into long-established laboratories is prevented.

R. W. Cahn

# Snail-paced parasite that is marching through South America

Schistosomiasis, otherwise known as Bilharzia, is a debilitating disease causing anaemia, diarrhoea, abdominal pain and sometimes death. Its spread, initially through a particular species of freshwater snail, is now being accelerated by human carriers—Brazil's millions of migrant workers

Report by **David Bousfield** of Sussex University

UNTIL the 1920s schistosomiasis, a debilitating parasitic disease caused by *Schistosoma mansoni* which is transmitted by certain species of freshwater snail, was more or less restricted to the north-east of Brazil—an area which includes the states of Ceará, Rio Grande do Norte, Paraíba, Pernambuco, Alagoas and Sergipe. Then, as now, sugar cane cultivation along the coastal 'zona da mata' was a major source of employment. The sugar mills or 'engenhos' were invariably associated with river valleys providing alluvial fertilisation during the winter, water for irrigation, and ideal habitats for *Biomphalaria glabrata*, the main intermediate host of schistosomiasis in the area, which is capable of adapting to almost any kind of freshwater environment. Inland the climate becomes progressively drier and the corresponding vegetational zones, the 'agreste' and the 'sertão', supported simple farming and cattle ranching. In these semi-arid regions limited and intermittent sources of water meant concentration of population, pollution and disease and provided an environment for an intermediate host, *Biomphalaria straminea*, that was well adapted to temporary desiccation. Today, estimates for the levels of infection in Sergipe and Alagoas are above 30%, and even in the most developed state, Pernambuco, the level was almost 16% before 1975.

Unfortunately the disease did not remain in the north-east. Competition from the more progressive plantation owners in the south closed many 'engenhos' and forced others to adopt more mechanised, less labour intensive methods, whilst in the interior the severe droughts of 1958 and 1970, together with the 'strong-arm' tactics of the richer landowners forced many 'nordestinos' off their land and on to the road. These migrants travelled mainly to the south in search of work, taking their diseases with them. During the 1970 drought, for example, out of the total population of 30 million, 2 million people left the north-east. In 1937 schistosomiasis reached the state of Minas Gerais, and the states of Rio de Janeiro and São Paulo in 1950. In 1953

the disease reached Paraná bordering with Argentina and Paraguay, and it was recorded in Brasília in 1973. Since potential intermediate hosts were already to be found in all of these states it is presumed that human migration was responsible for the spread of the disease. By 1975 it was estimated that there were between 8 million and 18 million carriers and the disease cost \$150 million per year.

Human migration, however, is not the only reason for the rapid increase in size of the endemic area. Until about two decades ago only *Biomphalaria glabrata* and *B. straminea* were recognised as being the important intermediate hosts for schistosomiasis in South America. A third species *B. tenagophila*, found only in the south of the country (but whose distribution stretches westward and southward into neighbouring Bolivia, Paraguay, Argentina and Uruguay) was thought to have a very low susceptibility to infection by the miracidia of *S. mansoni*. Indeed in 1923 the Brazilian taxonomist Adolpho Lutz had proposed that the species be called *Planorbis immunis*. In 1956, however, Lygia Corrêa and others found a number of foci in the Paraíba valley which were maintained solely by *B. tenagophila*—in some areas snail infection rates were as high as 48%. Subsequent laboratory work conducted by Lobato Paraense and his co-workers have shown that *S. mansoni* is gradually adapting to its new snail host and that in the case of the strain from the Paraíba valley this process is particularly well advanced.

## Will the strain spread to Amazonia?

In a recent paper by Paraense and Corrêa they remark that "the susceptibility of most *B. tenagophila* populations to the S. J. [Paraíba] strain points to a fact of practical significance—the possibility of expansion of that strain to a wide South American area, most of which is still free of schistosomiasis". They also report that the strain is gradually spreading, and that this rate will increase as stronger migration incentives and better economic opportunities are developed in the region.

Brazil's waterside shanty towns: a focus for transmission of disease

In addition to this movement south, spread of schistosomiasis has been recorded, albeit on a much smaller scale, in the northern states of Maranhão and Pará. The intermediate host here is *B. straminea* but a new potential host *B. amazonica* has recently been discovered to the west with a distribution stretching from Porto Velho, along the Rio Solimões to Manaus. The possibility of spread to Amazonia is generally acknowledged amongst public health workers to be small. This judgement is based on the low population densities and high flow volumes involved, and the unsuitability of the water chemistry. However, the development of the Transamazonian Highway, built specifically to act as a 'safety valve' for the drought-plagued northeast, must challenge some of these assumptions. The original project, announced in 1970, called for settlement of 100,000 families along the pioneer highway by 1976—although, in fact, by September 1977 only 5,333 had actually been settled. Small towns were constructed every 10 km (agrovilas) with larger administrative and manufacturing centres built at 100 and 400 km intervals. Research conducted by Dr Nigel Smith (INPA, Manaus), however, has shown that as of September 1974 only 4 out of 26 agrovilas were equipped with piped water and

only 10 out of 26 possessed privies. Gastrointestinal problems due to the use of water from streams and ponds contaminated by human and animal faeces are already one of the major reasons for hospital admission. SUCAM, the government organisation responsible for disease control, maintains surveillance at Marabá, Altamira and in Rondônia, but to date no transmission has been reported, although many of the settlers are infected. However, at SUCAM's headquarters in Brasília, Dr Solon Camargo pointed out to me that agricultural activity and other attempts to modify forest ecology might produce favourable snail habitats in the vicinity of the highway. According to Dr Smith the 'slash and burn' techniques of the settlers and the application of lime to the soil has produced a large modification in the chemistry of stream and pond water close to the road and at a number of sites, notably Altamira *B. straminea* populations already thrive.

Until 1975 attempts to control Brazilian schistosomiasis took the form of small pilot projects usually aimed at reduction or eradication of snail populations using molluscicides. Some attempts to reduce the incidence of the disease by chemotherapy had also been made but neither strategy had been particularly useful in controlling transmission—small residual populations of infected snails could still maintain high rates of transmission and treated patients soon became reinfected, although it might be several years before disease reached its more advanced forms again. Indeed by this time many Brazilians working in schistosomiasis control felt that attempts to reduce the disease should be linked to community health programmes, and in particular to the provision of piped water, toilets and communal laundries. In rural Brazil

75% of households were without any form of toilet and 71% without protected water supplies in 1975. Dr F. S. Barbosa, a specialist in snail control wrote in 1974 that "attempts to control schistosomiasis, in a large scale, by using the conventional single control methods are futile and, more than this, may become detrimental to the developing communities."

### Better sanitation key to prevention

When the first national plan to control schistosomiasis (PECE) was announced in 1975 at the beginning of the term of office of President Geisel it was greeted by considerable criticism from the scientific community, for the Minister of Health, Dr Paulo de Almeida Machado proposed the eliminate, or at least control, the disease by mass chemotherapy—the drug oxamniquine (Mansil) being used most extensively. This choice of strategy was based on the success of a small pilot scheme in Paraná and the success of of an earlier mass injection scheme in which 80 million people were vaccinated against meningitis in 10 months. It is probable too that the need for positive results before the next election in 1978 played a part in the design of the programme. PECE began with two closely monitored experimental projects—one at the town of Tourós (population 2,250) in the state of Rio Grande de Norte, and the other at Santo Antonio das Trempes (pop. 571) in Pernambuco. At Tourós almost all the population was treated 'en masse' with oxamniquine during December 1975. Infection levels dropped from 56% to 5% but rose to 19% after one year. Indeed, for children under 15 years, the highest risk group, more than 50% became re-infected during this period. On the other hand, at Santo

Antonio das Trempes where chemotherapy was preceded by mollusciciding and installation of piped water, toilets, showers and communal laundries, the infection rate, which originally had been 50.4%, was still only 2% twenty months later. PECE has since been extended to cover seven north-eastern states, yet still relies heavily on drug therapy. Oxamniquine will be given to 12 million people (already between 1 and 2 million have been treated) whereas provision of sanitation is planned for only 2.6 million.

Additional programmes designed to control and stem the spread of schistosomiasis in the south are being undertaken by the São Paulo Secretariat of Health and in the neighbouring state of Paraná by SUCAM. São Paulo's problems began with its rapid industrial and agricultural growth with the concomitant need for manpower, irrigation systems and power stations. For example the state is now the country's biggest producer of sugar cane, a crop whose importance to the national economy will increase rapidly as the government's programme to substitute ethanol, produced from sugar, for gasoline gets under way. The need to reduce energy imports has also made hydroelectric power an increasingly attractive alternative and new schemes, such as the one at Itaipú, now have catchment areas extending into Argentina and Paraguay, making international transfer of schistosome strains a possibility. During the period 1967-70, the state received 113,054 migrants, mostly from the north-east and Minas Gerais. Routine coprological examination showed that an average 23% had schistosomiasis. By 1974 it was estimated that a quarter of a million infected migrants had entered the state. Attempts have been made to screen and treat infected migrants as they arrive. However, in order to prevent the spread of schistosomiasis such a scheme required that all migrants register with the local authorities, and that diagnosis and treatment are 100% effective. To date none of these standards has been achieved and the number of active foci within the state increases.

Whatever else happens in the future, it is clear that Brazil's need for cheap migratory workforces will continue to increase, and it is to be hoped that the new Minister of Health, Dr Mario Augusto de Castro Lima, with an extended 6 year term of office in front of him, will realise that chemotherapy is no match for the powerful social and economic forces which have made schistosomiasis a major problem in Brazil's agro-industrial age. □

Migrant sugar workers: attempts to screen them medically have failed

David Bousfield visited Brazil on a Nature Writing Fellowship

# Which researcher will get the grant?

*Jonathan R. Cole and Stephen Cole describe how disagreements among peer reviewers can explain the unexpectedly low correlation between a scientist's prior professional performance and his or her chances of being awarded a research grant.*

In recent years the system used by the United States government to distribute basic research funds for scientists has been under increasing attack both from members of the scientific community and from the American Congress. The most important criticism that has been raised is that the current system based upon peer review leads to inequitable decisions favouring eminent scientists and putting non-eminent scientists at a serious disadvantage in the competition for increasingly scarce funds.

For the past three years we have been conducting a detailed study of how the National Science Foundation decides whether or not to approve applications for research funds (Stephen Cole, Leonard C. Rubin, Jonathan R. Cole, *Peer Review in the National Science Foundation* (Washington: National Academy of Sciences, 1978)). We have done this work as consultants to the Committee on Science and Public Policy (COSPUP) of the National Academy of Sciences. Our study is based upon extensive qualitative interviews with people involved in all aspects of peer review, particularly NSF programme directors; an analysis of the actual reviews given to 250 research proposals; and a quantitative analysis of 1,200 applicants to 10 different NSF programmes in fiscal year 1975. The purpose of the quantitative study was to identify those characteristics of scientists and their 'track records' that were correlated with high or low peer ratings and with the final funding decision.

## 'Old boys club' theory disproved

Although the NSF peer review system had been criticised as being an 'old boys' club', our research did not support the contention that the methods used by the NSF in deciding who should receive funding were inequitable. We found that eminent reviewers did not favour applications from their eminent colleagues. Furthermore we found weak correlations between measures of the scientific performance of the applicant and the peer review ratings they received. Finally we found that the peer review ratings did in fact almost completely determine whether or not a grant was funded or declined funding.

One important result of the first phase of our finding of the first phase of the research concerned the relationship of past 'track record' of the applicant to the peer review ratings they received. For example, we found that the number of papers published in the last 10 years and citations to those papers had only a slight influence on ratings given to a proposal by the peer reviewers. In two of the 10 programmes we studied the proportion of variance explained on ratings by citations were 0.16 and 0.14, and in the other programmes less than 0.10. Other productivity or output measures are even less strongly related to the ratings.

We also found that the prestige rank of the applicant's current academic department had only a small to moderate correlation with the ratings given to their proposals. The criticism that applicants from prestigious East and West coast universities have a significantly better chance of receiving grants than those from other universities turned out to be unjustified.

In this discussion our primary concern is why we did not find the expected relationship between measures of the scientist's past performance, his position in the stratification system of science, and the peer review ratings received on his proposal.

One reason why the characteristics of applicants showed such low correlation with ratings received was that there was an unexpectedly large amount of disagreement among reviewers of the same proposal. Some reviewers gave proposals high ratings and other reviewers gave the same proposal low ratings. If the same applicant gets high ratings from some reviewers and low ratings from others, the correlation between any characteristic of the applicant and the ratings must necessarily be low.

In order to estimate the level of

agreement among reviewers of particular proposals we performed a one-way analysis of variance for each of the 10 programmes. In this analysis, the dependent variable was the rating that a proposal received from a reviewer; the independent variable was simply the proposal number, which is of course a nominal variable. The results presented in the accompanying table (overleaf) show the proportion of the total sum of squares for ratings on all proposals that is attributable to disagreements among reviewers of the same proposal.

## Lack of consensus is common to all subjects

Take, for example, the algebra programme at the NSF. If we examine all the variation that exists among raters of all proposals to the algebra programme, we find that 45% of the total variation is due to disagreements about the quality of individual proposals among the peer reviewers of the same proposal. The level of disagreement among reviewers of algebra proposals was by no means anomalous. We should also point out that contrary to our expectations there was no less consensus in the social sciences such as anthropology and economics than there was in the natural sciences. In fact, economics was the programme which showed the lowest proportion of variance (35%) explained by within-proposal variations.

These disagreements could be the product of several processes. First, there is substantially more actual cognitive disagreement among reviewers about the merits of proposed work by the applicant than is often believed to be the case. Second, the high amount of disagreement among reviewers could be in part a result of intersubjectivity, that is, two scientists might actually

Consensus among reviewers and influence of applicant characteristics on peer review ratings

	Lack of consensus among reviewers		Pearsonian correlation coefficients between				
	Percentage of total variance due to within-proposal variance	Log of citations to recent work and individual ratings	Log of citations to recent work and mean ratings	Rank of dept and individual ratings	Rank of dept and mean ratings	Combination of 9 characteristics and individual ratings*	Combination of 9 characteristics and mean ratings*
Algebra	45	.06	.11	.07	.10	.17	.31

Solid-state physics	55	.08	.16	.08	.16	.17	.38

\* The nine characteristics include: professional age, rank of Ph.D. department, rank of current department, academic rank, log of papers published in last 10 years, log of citations to work published in last 10 years, log of citations to papers more than 10 years old, whether institution is a Ph.D.-granting one or other, number of years funded by NSF in last five years.

have the same substantive appraisal of a proposal but may use different subjective scales of evaluation. Consequently, a similar evaluation can result in different actual ratings. Third, the disagreements could reflect some personal bias that the reviewers have against a particular principal investigator who submits a proposal. We could catalogue other potential sources of variations in the ratings, but the important, albeit tentative conclusion to underline is that the amount of variation in peer review ratings that could possibly be explained by characteristics of scientists and their track records is distinctly limited by this disagreement among reviewers over the same programme.

## Taking published papers into account

In order to eliminate the effects of this lack of consensus on the correlation between applicants' characteristics and ratings, we used as the dependent variable the mean rating received. As independent variables we used the log of citations to papers published during the last ten years prior to application, rank of the applicant's academic department, and a combination of nine characteristics measuring the scientist's location in the stratification system of science. The results of these regression analyses appear in the table.

Given that about one half of the variance in ratings is the result of within-proposal disagreement, the correlation between the characteristics of the applicant and the mean rating is about double the correlation between characteristics of the applicant and the individual rating. Although the correlations between individual characteristics and mean ratings are higher, they are still not as high as one might expect, particularly in fields such as solid state physics, algebra, or chemical

dynamics.

There are three reasons why these correlations are not higher. The first we call *self-selection*. Not everyone who is eligible to apply for an NSF grant does so. The group of scientists that applies for NSF research money tends to be a self-selected group of the most creative and productive scientists in their particular fields. In order to apply for a grant, an applicant must write a proposal that he or she knows will be sent out for review to colleagues in the discipline. Scientists who do not have active, ongoing research programmes are less likely to write such a proposal and subject themselves to peer review than those who do have active research programmes. Data in which we compare the productivity of the applicants to the NSF with productivity of random samples of academic scientists indicate that NSF applicants are on the whole a more productive group than are the population of scientists in a given field. Because self-selection takes place, the group of applicants from whom the reviewers must select successful proposals tends to have attenuated variance on some of the independent variables.

One reason for the low correlation between the rank of an applicant's academic department and peer review ratings is the relatively wide distribution of academic talent among American universities. Although it is true that, on the average, highly prestigious departments have more talented and productive scientists, a significant proportion of talented scientists are not located at the most prestigious departments. Several independent studies have found that the correlation between citations to a scientists' work and the prestige rank of his department is 0.30 or less. This suggests that quite a few scientists who have produced work judged to be useful and of high quality are not in highly ranked departments.

When we relate the low correlation between the quality of an individual scientist's research output and the rank of his department to the concept of self-selection, we can understand better the low correlation between the rank of an applicant's department and peer review ratings. If every scientist in every department applied for a grant, there would probably be a considerably higher correlation between rank of department and rating. But we know that all scientists do not apply. Applying scientists from low-ranked departments are probably the most active researchers of those departments. Whereas six mathematicians from MIT may apply for NSF funds in a given year, perhaps only one mathematician at a lower-ranked department will apply. But this one individual may have a national reputation comparable to those of some of his colleagues at high-ranked departments.

## Quality of science is main influence

Finally, the third and perhaps most important reason for the low correlation between characteristics of the applicants and peer review ratings is that all evidence collected thus far in the peer review study suggests that the ratings are strongly influenced by the reviewer's perception of the quality of the science contained in the proposal. If this is indeed true and the correlations between the ratings and the characteristics of applicants are low to moderate, this would necessarily mean that the correlation between characteristics of applicants and the perceived quality of their proposals would be low to moderate. We are currently analysing a set of data which will allow us to determine the extent to which this hypothesis is correct and the meaning of these data for peer review and the distribution of federal funds to research scientists. □

## Temperatures in the clouds of Venus

from P. J. Houghton

ON board the Pioneer Venus orbiter which encountered the planet Venus on 4 December 1978 was a multi-channel infrared radiometer jointly built by the Jet Propulsion Laboratory, Pasadena, California and the Department of Atmospheric Physics at the University of Oxford. The Oxford contribution to this radiometer is the first British built experiment to leave the vicinity of the Earth and travel to one of the planets. Remote sounding observations with this radiometer have already provided the first information on the temperature structure in the upper Venus atmosphere (Taylor *et al.* *Science* **203**, 779; 1979). On page 613 of this issue of *Nature* Taylor and his colleagues at the Jet Propulsion Laboratory report some interesting new measurements of the detailed thermal structure of the clouds near the Venus pole which provide important clues to the nature of the circulation of the Venus atmosphere. Investigations from Earth-based telescopes and from spacecraft have demonstrated the very deep, rather uniform cloud cover on Venus, which completely obscures the surface from view. That the cloud droplets mainly consist of sulphuric acid was discovered as a result of the interpretation by Hansen, Arking and Young in 1973 of polarisation observations made at different phases of Venus by the French astronomers Coffeen and Gehrels in 1969. Although the size of the particles, as also deduced from these measurements, turned out to be a few microns only, the question remained as to how the upward motion necessary to maintain the clouds was generated, even though for such small particles the amount of upward motion need only be very small. A further question concerned the location of the compensating regions of downward motion. This week's report gives support to the theory put forward by Murray *et al.* (*J. geophys. Res.* **68**, 4813; 1963) and Suomi and Limaye (*Science* **201**, 1009; 1978) that intense regions of downward motion might be concentrated near the poles. In these regions clearing of the clouds might be expected, which would

not be visible from Earth because the polar regions are viewed so obliquely.

The Pioneer 12 orbiter, because it goes nearly over the Venus pole, has provided the first opportunity to observe the polar regions in detail. The infrared radiometer observations clearly show a localised region of much higher temperature than the rest of the cloud cover which has been interpreted as a local clearing of at least the upper half of the cloud layer. The measurements do not rule out a clearing to much deeper levels.

Observations from the infrared radiometer at altitudes of 60–90 km in the Venus atmosphere, well above the main cloud deck, have shown a temperature contrast of about 20 K between equator and pole, with the pole being warmer (Taylor *et al. op. cit.*). The obvious interpretation of these measurements in terms of circulation is of a Hadley type circulation with rising air over the equator, cooling as it rises, and sinking air around the polar regions, warming as it sinks. This is not unlike the thermally driven circulation which occurs in the mesosphere of the Earth's atmosphere where very cold temperatures occur at the mesopause (~85 km altitude) in summer contrasted with much warmer temperatures near the winter mesopause in the other hemisphere. Another important feature of the circulation at those levels above the main cloud deck is the very rapid zonal motion which occurs. Air moves around the planet at a velocity of about  $100 \text{ ms}^{-1}$ , one rotation of the planet taking about 4 days. This rapid motion ensures that there is little temperature contrast between the day and night side of the planet, as is confirmed by the Pioneer radiometer observations.

The solid surface of Venus rotates only very slowly—once in 243 days—so that the comparatively rapid rotation of higher parts of the Venus atmosphere is particularly intriguing. Schubert and Whitehead in 1969 (*Science* **153**, 71) put forward a possible theory of the mechanisms driving this circulation; they suggested it was in-

duced by a travelling thermal wave induced by the motion of the Sun relative to the atmosphere.

At altitudes above about 90 km in the Venus ionosphere, the thermal contrast between equator and pole largely disappears. Instead at these levels, as is shown again from infrared radiometer measurements, a temperature difference of about 20 K exists between the day and night side of the atmosphere, indicating a mean circulation which is primarily occurring between the warmer sunlit side and the cooler dark side.

It will be interesting to discover, from further work on the data from the infrared radiometer and from the other instruments on the Pioneer 12 orbiter, whether there is any evidence for large scale waves in the atmosphere above the Venus clouds of a similar or different nature to the planetary waves observed in the Earth's atmosphere. A big question which clearly arises is: how are the circulations in different parts of the Venus atmosphere linked? Is the upper atmosphere circulation, for instance, driven from below, or is it driven by heat sources and sinks near the cloud tops? A particularly interesting observation is that the cloud clearing reported in this issue is not actually at the pole but some  $10^\circ$  from it, suggesting that the circulation may have some interesting asymmetrical properties. Clearly a lot remains to be understood that will not only encourage those working on Venus data to extract from it information which will provide clues to some of the intriguing problems of the Venus circulation, but also provide the theoretical modellers with a challenge to fit it all together. As we begin to understand how the motions are organised in the Venus atmosphere, which is so different from our own, we shall in turn acquire deeper insight into what goes on in the atmosphere of the Earth. □

# Neoplasias and B-cell precursors

from Maxime Seligmann

THE earliest recognisable cells within the B-cell differentiation pathway are known as pre-B cells. They are found in the fetal liver of rabbits, mice and men and are characterised by the presence of intracytoplasmic IgM and the lack of surface receptors<sup>1-3</sup>. In adults, pre-B cells are found almost exclusively in the bone marrow<sup>4</sup>. IgM can be detected by immunofluorescence techniques in the cytoplasm of most, if not all, large rapidly dividing pre-B cells and their small non-dividing pre-B cell progeny<sup>5</sup>, with an unusual perinuclear and reticular staining pattern. Pre-B cells are the progenitors of surface Ig positive B lymphocytes but, because they do not express functional immunoglobulin receptors on their surface, it can safely be assumed that antigens do not influence the diversity of immunoglobulins produced by pre-B cells. Various studies suggest that clonal diversification is accomplished by the pre-B cell stage. For example, individual pre-B cells show allelic exclusion in rabbits heterozygous for kappa chain allotypes<sup>6</sup>. In myeloma patients, antibodies specific for idiotypic determinants of the myeloma globulin stain bone marrow cells with pre-B cell characteristics<sup>7</sup>; this finding provides evidence that pre-B cells belong to the neoplastic clone and suggests that V-C joining has occurred at this stage.

Several recent studies have shown that some murine and human neoplasias involve such early B-cell precursors which produce cytoplasmic immunoglobulin in the absence of membrane-bound immunoglobulin molecules. The Abelson murine leukaemia virus complex, which consists of a replication-defective virus and its helper Moloney leukaemia virus, causes thymus-independent lymphomas in Balb/c mice, and several characteristics suggested that these tumours were related to the B-cell lineage<sup>8</sup>. Two independent studies<sup>9,10</sup> have recently provided evidence that several neoplastic cell lines resulting from *in vivo* or *in vitro* transformation by Abelson virus have features indicative of early maturation compartments in the B-lymphocyte lineage. On the other hand, two human lymphoid cell lines (Raji and T51) were also shown to express characteristics of early B-cell precursors<sup>11</sup>. Finally the

leukaemic cells of some patients with acute lymphoblastic leukaemia also display features thought to be characteristic of pre-B cells. This pre-B cell phenotype is not uncommon because it was found in four of 22 patients in the initial report by Vogler *et al.*<sup>12</sup> and in 10 of 68 patients in the subsequent series of Brouet *et al.*<sup>13</sup>.

The results of immunofluorescence and immunoglobulin synthesis studies suggest that the maturation arrest in these various neoplastic cells may occur at slightly different steps in the early stages of the B-cell pathway. Early studies indicated that normal pre-B cells produce complete monomeric IgM molecules with both  $\mu$  and light chain<sup>1,2</sup>. In contrast, no light chain determinants could be detected by immunofluorescence in most human leukaemic pre-B cells<sup>13</sup>. This negative finding could be due to limitations of immunofluorescence technology because, in the human cultured cell lines mentioned above, light chains could not be detected by immunofluorescence but were found at the ultrastructural level by an immunoperoxidase method<sup>14</sup>. It should be noted, however, that the number of normal pre-B cells containing detectable light chain determinants is lower than the number of such cells with detectable  $\mu$  chains<sup>14</sup>. This discrepancy and the findings in acute lymphoblastic leukaemia are consistent with the possibility that there is an asynchronous onset of heavy and light chain synthesis. The data reported by Siden *et al.*<sup>10</sup> support this hypothesis because most Abelson-virus-induced cell lines synthesise a  $\mu$  chain but no

detectable light chain. This  $\mu$ -only phenotype was stable on subcloning. Cultures in which synthesis of both  $\mu$  and  $\kappa$  chains occurred showed a rapid loss of  $\kappa$  chain synthesis. One line was studied in detail: the intracytoplasmic molecules represented glycosylated  $\mu$  chain dimers which were not secreted. Light chain synthesis could not be induced by reducing the growth rate of the cells, a procedure that resulted in increased  $\mu$  chain synthesis. In contrast to these findings, another Abelson-virus-derived line studied by the same authors produced only  $\kappa$  chains. It should be emphasised that the biosynthesis experiments showed that the cytoplasmic extract contained, in addition to the  $\kappa$  chain band, a slower band which comigrated with a precursor polypeptide. It is interesting in this respect that the intracytoplasmic IgM of the human lines was not located inside endoplasmic reticulum but at the level of free polyribosomes<sup>11</sup> and that these lines produce abnormally large Ig polypeptide chains (unpublished results of P. Guglielmi and J. L. Preud'homme). The two Abelson-virus-transformed cell lines studied by Boss *et al.*<sup>9</sup> apparently synthesised monomeric IgM with both  $\mu$  and light chains. However, most cells in both lines were presumably less mature than pre-B cells because they were negative for cytoplasmic IgM but could be induced to express IgM positivity by several compounds such as lipopolysaccharide, DMSO and butyric acid. The human lymphoid cell lines are presumably slightly more differentiated than *bona fide* pre-B cells because they bear Ia-like determinants, they secrete polymeric IgM molecules (instead of monomeric IgM in normal pre-B cells<sup>2</sup>) and they become able to produce membrane-bound immunoglobulin molecules in certain conditions (unpublished results of P. Guglielmi and J. L. Preud'homme).

Another point of interest is that human pre-B leukaemic cells in a fair percentage of patients<sup>13</sup>, as well as several Abelson virus-induced tumours<sup>15</sup> and normal pre-B cells (G. Janossy, personal communications), were shown to contain low but detectable levels of terminal deoxynucleotidyl transferase. This enzyme was initially considered as characteristic for thymic and pre-thymic cells but it is probably present in progenitors of all lymphoid cells, a finding which might be related to the possible role of this enzyme in the generation of somatic mutations<sup>16</sup>.

The availability of tumour cells and continuous lines corresponding to early precursors of the B lineage lymphoid cells should be useful for the study of immunoglobulin gene diversification and expression. □

## Hepatitis A: a giant leap forward

from Arie J. Zuckerman

THE past decade has seen rapid progress in the identification of viruses causing hepatitis in man, starting in 1968 with the discovery of the association between Australia antigen and hepatitis type B (serum hepatitis). Five years later, hepatitis A virus, which is the cause of infectious or epidemic hepatitis, was identified by electron microscopy in faecal extracts, and more recently evidence has been obtained of a third type of hepatitis (so called non-A, non-B hepatitis) which is probably caused by more than one virus. The worldwide research effort which has been devoted to the problem of viral hepatitis by epidemiologists, virologists, molecular biologists, immunologists, pathologists, clinicians, blood transfusion services, public health authorities and others reflects the impact which these viruses have on human health and welfare. Although remarkable advances have been made in the characterisation of the biophysical and biochemical properties of hepatitis A and B viruses, reproducible propagation of these viruses in tissue culture has defied every effort and continued to elude even the most stubborn research worker. Provost and Hilleman (*Proc. Soc. exp. Biol. Med.* **160**, 213; 1979) now report the first reliable serial cultivation of human hepatitis A virus in primary explant liver cell cultures of marmosets and in a fetal rhesus kidney cell line. This work represents a spectacular advance in a hitherto frustrating and seemingly insoluble problem.

The events which led to this success started in 1967 when Deinhardt and his associates (*J. exp. Med.* **125**, 673; 1967) transmitted human hepatitis A virus to two species of marmosets, which are small South American monkeys, and the infection was transferred serially from animal to animal. Differences in susceptibility to hepatitis A exist between the marmoset species, with *Saguinus mystax* being the most susceptible. In 1973, the CR 326 strain of hepatitis A virus was isolated in *S. mystax* by Mascoli *et al.* (*Proc. Soc. exp. Biol. Med.* **142**, 276; 1973) from naturally occurring outbreaks in Costa Rica, and the virus was further characterised in the sera and livers of

the marmosets (Provost *et al.* *Proc. Soc. exp. Biol. Med.* **148**, 532; 1975). By then sensitive serological tests for hepatitis A virus and its antibody became available and the susceptibility of chimpanzees as well as the susceptibility of a more readily available rufiventer-like marmoset designated as *S. labiatus* (also known as *Marikina labiata*, *Jacchus rufiventer*) was described (Provost *et al.* *Proc. Soc. exp. Biol. Med.* **155**, 283; 1977).

Using the CR 326 strain of human hepatitis A virus passaged five times in *S. mystax* and 26 times in *S. labiatus*, Provost and Hilleman inoculated normal liver explant cell cultures obtained from *S. labiatus* with the virus, and observed by direct immunofluorescence minute fluorescing cytoplasmic granules in some of the hepatocyte-like epithelial cell outgrowths as early as 8 days after inoculation. The number of the affected hepatocyte-like cells and the number of fluorescent granules increased with time so that when cultures were collected on day 23, 75–100 % of these cells, but not other cell types, contained large numbers of granules. There were no cytopathic changes. The virus was identified as hepatitis A by various techniques including specific immunofluorescence blocking, serum neutralisation, immune adherence haemagglutination and radioimmunoassay; and the virus was passaged serially five times. Because the availability of marmosets is very limited, an alternative cell culture system was sought. The virus propagated in primary kidney cell cultures of *Cercopithecus aethiops* (grivet or green monkey), but many of the cultures contained cytopathic adventitious agents of endogenous origin. Consequently, Provost and Hilleman used cultures of fetal rhesus kidney cells (designated FRhK6 cell line), which are epithelial-like but have only a maximum population doubling of 12. Specific immunofluorescence was detected in these cells as early as 3 days after inoculation and occurred throughout the cell sheets during the following weeks. Cytopathic changes were not observed. The virus was passaged serially, the incubation period for development of fluorescence was shortened, and there was a larger yield in these cells than in the liver cell explants. Titration of infectivity of the virus collected in the fifth and sixth passage yielded titres of  $10^6$ – $10^7$  infectious units per ml respectively, and virus in the fifth passage collection retained the ability to infect *S. labiatus* marmosets. The virus was successfully transferred through eight serial passages in which the calculated dilution of the original inoculum was  $2.9 \times 10^{-20}$ .

The importance and practical significance of this work can be summarised as follows: the means may now be available for detecting human hepatitis A virus *in vitro*, for preparing large quantities of viral antigen for serological tests and for providing a source of viral antigen for the preparation of vaccines against an important infection which is endemic in all parts of the world.

However, answers to several questions are still required. Can the virus be cultivated from naturally occurring strains without adaptation by serial passage through susceptible marmosets and what is the minimum period of adaptation required; can hepatitis A virus be propagated in more readily available cell lines with longer population doubling times? Provost and Hilleman provide a hint that this may be so because the virus replicated to a limited extent in human diploid lung fibroblasts, which are commonly used for the preparation of vaccines. The way may thus be open in the near future to the effective control of epidemic hepatitis. □

## Vacancies in nickel-aluminium and other alloys

from Robert W. Cahn

IN 1937 the metallurgist A. Taylor made a celebrated study of the structure of nickel-aluminium alloys; this called for great experimental precision, and in 1972 he returned to the problem and examined it with even greater scruple (Taylor and Doyle, *J. appl. Cryst.* **5**, 201; 1972). This second study may be said to have launched a new wave of research on the Ni–Al system and its analogues, even though few of the most recent protagonists seem to be aware of Taylor's second study.

Taylor's experiments centred on the alloy  $\beta$ -NiAl, which adopts the very simple B2 (CsCl-type) structure: nickel atoms at cube corners, aluminium at cube centres. Taylor measured macroscopic densities and lattice parameters as a function of composition, either side of the 50/50 composition: by putting together the two sets of measurements, he was able to deduce the destinations of excess nickel or aluminium atoms. On the nickel-rich side, the extra nickel atoms substitute in the usual way for aluminium atoms on the aluminium sublattice. The aluminium-rich side, however, is quite different: no aluminium substitutes on the nickel sublattice, instead nickel atoms disappear from the nickel sublattice, leaving nickel vacancies. For instance, at 45

Arie J. Zuckerman is Professor and Director of the Department of Medical Microbiology and the WHO Collaborating Centre for Reference and Research on Viral Hepatitis at the London School of Hygiene and Tropical Medicine, University of London.

at. % Ni, 18 % of the nickel sites are vacant, all of the aluminium sites are filled. Such vacancy populations, determined by composition and not temperature, are distinguished as constitutional vacancies.

Several other studies showed that stoichiometric  $\beta$ -NiAl quenched from a high temperature (as opposed to that slowly cooled) contained a high concentration of thermal vacancies; the most recently cited figure is 1.08% of vacancies at 1,600 °C. This is a very much larger thermal vacancy concentration than is found in other metals or alloys, even just below the melting temperature; so large that on cooling the vacancies will separate out into a population of voids visible in the electron microscope (Epperson *et al. Phil. Mag.* **A38**, 529; 1978). 50/50 NiAl containing such vacancies, all on the nickel sublattice, must also contain substitutional defects—that is some nickel atoms in the aluminium sublattice, also called nickel antistructure atoms—to preserve the overall chemical composition: specifically, two vacancies must be accompanied by one substitutional defect. Such a trio of linked defects is now termed a triple defect and much recent research has centred on this entity.

In recent years, investigators in the US, England and Germany began to look for parallels to this curious behaviour in alloy systems isomorphous with  $\beta$ -NiAl, and attention soon centred on NiGa and CoGa. It became clear that these two phases always contain triple defects, even when they have been cooled slowly to eliminate thermal vacancies as far as possible. Though there has been some confusion in the literature on this point, it is now adequately clear that the triple defects in these alloys at 50/50 composition are indeed wholly of thermal, not constitutional origin; it is impossible to eliminate all thermal defects, even by very slow cooling.

A study of NiGa by Donaldson and Rawlings (*Acta Met.* **24**, 811; 1976) again made use of measured densities and lattice parameters to assess just how the concentration of nickel vacancies and gallium antistructure atoms varies with composition. To obtain these values, they developed an iterative method of calculation, starting out with an arbitrary assumption about the number of triple defects at stoichiometry, and refining this value in cycles until experimental densities and lattice parameters at a range of compositions could be matched. (To do this, it is necessary to assume a value for the relaxed volume of a nickel vacancy, which has to be based on theoretical

estimates, and comparison of some recent papers shows that this is the weak link in the chain of theoretical deduction.) Donaldson and Rawlings found just over 3% of vacancies and half that number of antistructure atoms in 50/50 NiGa. At 47% Ni, there are 7% vacancies and 0.2% antistructure atoms, while at 54% Ni, the defect numbers are 1% and 4.5% respectively. The triple defect itself (a 2/1 ratio of the two kinds of defect) only exists at stoichiometry. Ho *et al. (Scripta Met.* **11**, 1159; 1977) obtained rather similar values, though they do not match Donaldson's and Rawlings' figures in every particular.

Berner (dissertation, Stuttgart, 1976; Berner *et al. J. Phys. Chem. Solids* **36**, 221; 1975) has found closely similar values for defect densities in CoGa.

The computational problem of determining defect concentrations from experimental data when both defect types are present has now been eased by an ingenious application of statistical thermodynamics to the problem. Edelin (*Acta Met.* **27**, 455; 1979) calculated the relations between composition, defect concentrations and defect formation energies, using merely the hypothesis that the formation energies for Ga vacancies and antistructure atoms on the Ni (or Co) sublattice are so much higher than the energies for Ni (or Co) vacancies and antistructure atoms on the Ga sublattice that the former two defects never appear in detectable numbers. Edelin showed that the variation of concentration of the two defect types, both as a function of temperature and as a function of composition, was determined by a single composite activation energy,  $Q$ , and  $Q$  can be determined directly by fitting, for a range of compositions, experimental values of density and lattice parameter to his theoretical equations. Further, it appears that when fitting is done in this way, the relaxed volumes of vacancies and of antistructure atoms can be deduced from the measurements and do not need to be used as assumed input values. (This claim seems so remarkable that it deserves critical appraisal by a suitably qualified theoretician: it would seem to be the first claimed method for deductively obtaining relaxed defect volumes from experimental data.)

The claim by Edelin to be able to measure the relaxed volumes of defect sites is of particular interest because it has been established, from diffuse X-ray scattering measurements made at Stuttgart, that the lattice near a vacancy in NiAl or CoGa is severely distorted in a [111] direction. This distortion is of the same type as is found in a  $\beta \rightarrow \omega$  phase transformation. Such distortions must surely affect the relaxed vacancy volume (Ortiz and Ep-

person, *Scripta Met.* **13**, 237; 1979, for NiAl; Kirchgartner and Gerold, *J. appl. Cryst.* **11**, 153; 1978, for CoGa).

The composite activation energy,  $Q$ , found by Edelin for NiGa is 0.29–0.32 eV per atom and for CoGa, 0.265 eV per atom. These very low values account for the high thermal defect concentrations found even at stoichiometry in these two alloys. Edelin's method has not been used for NiAl (no accurate measurements of thermal defect concentrations at stoichiometry being available), but  $Q$  can be estimated from measurements of nickel diffusion in NiAl at a range of compositions (Hancock and McDonnell *Phys. Stat. Sol. A* **4**, 143; 1971). On the low-nickel side, it is assumed that the measured activation energy for diffusion is purely that for vacancy migration (because there is an abundance of constitutional vacancies available); then it is possible to compute the formation energy for thermal vacancies by subtracting the migration energy from the measured activation energy for diffusion at stoichiometry (where no constitutional vacancies exist). This approach gives 0.70 eV per atom, corresponding to the much smaller thermal vacancy concentration in this alloy. This much higher  $Q$  value also accounts, by way of Edelin's theory, for the virtual absence of aluminium antistructure atoms on the nickel-poor side in this alloy series, as contrasted with NiGa.

There have been several attempts to bypass the density/lattice parameter approach, which makes severe demands on experimental accuracy. (One difficult problem is to get precise densities in view of the presence of casting porosity in ingots; Taylor and Doyle overcame this by high-pressure annealing of ingots, and other investigators have sought to bypass it by using dilatometry instead of Archimedean weighing.) An alternative approach is to measure thermodynamic activities at high temperature and to relate such activities to defect concentrations. A theory to make this possible has been constructed by Neumann, Chang and Lee (*Acta Met.* **24**, 593; 1976) and has been applied to NiGa (Neumann *Scripta Met.* **11**, 969; 1977). The vacancy concentrations in NiGa alloys deduced from activity values are considerably lower than those obtained by the conventional method with quenched samples, but a very recent paper (Neumann and Chang *Z. Metallkde.* **70**, 118; 1979) shows that if allowance is made for loss of vacancies during quenching, then agreement is better. Nevertheless, it does seem that there must be some residual error in Neumann's statistical thermodynamics, and one possible source of such error is the tacit assumption that vacancies and antistructure atoms are randomly

disposed. Delavignette, Richel and Amelinckx (*Phys. Stat. Sol. A* **13**, 545; 1972) have adduced electron-microscopical evidence pointing to such order among the vacancies in hypostoichiometric NiAl, and Reynaud (*J. appl. Cryst.* **9**, 263; 1972) has evidence suggesting ordered antistructure atoms in hyperstoichiometric NiAl. Any short-range order among defects would have a considerable effect on thermodynamic activities. The recently observed anisotropic distortion around vacancies, already cited, with its associated stress field, could also affect activities. The activity method is therefore suspect, but it must be admitted that substantial order or lattice distortions could introduce errors into the density/lattice parameter method as well.

Surprisingly little attention has been paid to the question why  $\beta$ -NiAl, NiGa

and CoGa form defect structures at all. For instance, Massalski and Mizutani, in their survey of electronic structures of Hume-Rothery phases (*Prog. Mater. Sci.* **22**, parts 3/4; 1978) make no reference to these phases. Taylor and Doyle (*loc. cit.*) point out that the electron/atom ratio remains strictly constant at 3/2 from 50/50 NiAl to the phase boundary on the aluminium-rich side (where there are only 1.75 atoms per cell), and they assume this feature to govern the introduction of vacancies. The question then arises why other isomorphous alloy series such as Ni-Zn or Co-Be do not behave in this way. Machlin (*Scripta Met.* **13**, 123; 1979) has made an ingenious approach to this question by suggesting that the self-energy of the B (non-transition) component may be lowered by a reduction in the number of bonds between

B and transition metal atoms, resulting from the presence of transition metal vacancies adjacent to some B atoms. He is able to show that on this hypothesis, constitutional vacancies should be stabilised only for trivalent B metals, such as Al or Ga, and this is in accord with observation. There is scope for further theoretical treatment of the reasons for the formation of constitutional vacancies.

Clearly NiGa and CoGa in particular are ideally suited as test materials in which the predictions of precise statistical thermodynamics applied to defect populations can be compared with experimental observations. They are probably the best metallic materials for such comparisons, free of the complications arising from the need for charge neutrality which are unavoidable with ionic crystals. □

## Interferons and inducers *in vivo*

from Nowell Stebbing

MUCH is known about the mode of action of the interferons at the molecular level (Friedman *Bact. Rev.* **3**, 543; 1977), and intensive effort is being devoted to investigations of their structure and the cloning of the requisite genes. Although less attention has focused on the factors necessary for interferons to be effective in the treatment of virus infections, reports are now beginning to demonstrate the importance of host factors. The most recent such report (Shellekens *et al. Nature* **278**, 742; 1979) shows that interferon (from human leukocytes) is protective in monkeys against infection with a strain of vaccinia virus that does not respond to interferon in cultured cells. (The same cell lines are protected by the interferon against infection with vesicular stomatitis virus.) These results indicate that, *in vivo*, leukocyte interferon at least, has anti-viral effects by means other than the known molecular mechanisms. In view of the diversity of interferons in terms of immunological differences and cellular origin, it will be important to determine whether other interferons behave similarly, before these observations can be generalised. However, it is possible that the known molecular effects of interferons do not contribute directly to their anti-viral effects *in vivo* in any situation. Even when an interferon does inhibit virus replication in cell cultures, anti-viral effects in whole animals may be due entirely or in part to properties of particular cells of the host. Clearly, the anti-viral effects of interferons against infections of fibroblasts in culture should not be

extrapolated to treatments of whole animals, although this has been done for many years.

The issue of whether interferon inducers have anti-viral effects by means other than or additional to known molecular mechanisms has been highly contentious. Non-interferon-mediated anti-viral effects of polynucleotides have always been a possibility and claims that interferon induction is the sole mechanism of action have generally ignored the fact that such claims require quantification: it is necessary to know the extent to which observed anti-viral effects are due to interferon induction. It is now apparent that quantification by extrapolation from tissue culture studies is misleading. The most recent evidence in favour of interferon as the sole mediator of the anti-viral and anti-tumour effects of the double-stranded polynucleotide interferon inducer, poly(I):poly(C), is that of Gresser *et al. (Int. J. Cancer* **21**, 72; 1978). They demonstrated that anti-mouse interferon serum raised in sheep abolished the anti-viral and anti-tumour effects of poly(I):poly(C) administered to mice. However, mice treated with an anti-interferon serum, without simultaneous poly(I):poly(C) treatment, died earlier from virus infection than control mice and therefore the anti-serum may primarily affect virus- rather than poly(I):poly(C)-induced interferon. For such reasons it remains possible that poly(I):poly(C) has anti-viral and anti-tumour effects in addition to interferon induction.

Depletion of macrophages in mice obliterates the anti-viral effects of crude (macrophage) interferon and decreases the anti-viral effects of purified fibroblast interferon (Stebbing *et al. Inf.*

*Immun.* **19**, 5; 1978). Moreover, interferon and interferon inducers (Gidlund *et al. Nature* **273**, 759; 1978; Herberman *et al. Cancer Treatment Repts* **62**, 1893; 1978) are known to increase natural killer cell activity, implying that activities of these cells may be important for *in vivo* efficacy of interferons. Thus particular cell populations in whole animals seem to be decisive in determining the anti-viral and anti-tumour effects of interferons, and further work on the nature of their involvement would seem important for several reasons. It will of course be fascinating, to determine whether and in what ways the known molecular and cellular effects of interferons contribute to anti-viral and anti-tumour effects *in vivo*. In addition, clinical potential can only be determined by clinical studies whatever the theoretical arguments. However, it seems likely that the natural or induced immunosuppression associated with particular diseases could limit the efficacy of interferon therapy. The disappointment of negative results in clinical trials might be avoided by considering the state of cell populations necessary for *in vivo* efficacy of the interferon being tested. There is also the possibility of devising means of directly eliciting cell mediated anti-viral effects by short-circuiting the interferon mechanism.

Although interferon induction has generally been considered the means whereby polynucleotides have anti-viral and anti-tumour activity, other means are now apparent whereby even double-stranded polynucleotides could inhibit virus replication, for example by direct inhibition of protein synthesis (Levin & London *Proc. natn. Acad. Sci. U.S.A.* **75**, 1121; 1978; Kerr &

Nowell Stebbing is Director of Biology at the Research Division of Searle, High Wycombe, UK.

Brown *Proc. natn. Acad. Sci. U.S.A.* **75**, 256; 1978) possibly by means of a nuclease which degrades viral mRNA (Baglioni *et al. Nature* **273**, 684; 1978). The last possibility provides a mechanism for interfering with virus replication in a manner related to that of interferons and their inducers but without actual production of interferon. The anti-viral effects of single-stranded polynucleotides which do not induce interferon may occur by this means or by mimicking strategic nucleotide sequences in viral RNA (Stebbing *et al. Ann. N.Y. Acad. Sci.* **284**, 682; 1977). It is noteworthy that early studies on interferon induction by polynucleotides involved largely single-stranded RNAs (Isaacs *et al. Lancet* **ii** 113; 1963; Rotem *et al. Nature* **197**, 564; 1963) and that two separate mechanisms may have been involved in the overall anti-viral effect obtained. Induction of interferon was certainly a factor but independent more direct anti-viral effects may also have been involved. □

## Flattening of Uranus and Neptune

from David W. Hughes

PLANETARY flattening or oblateness,  $\epsilon$ , is defined as the difference between the equatorial and polar radii divided by the equatorial radius. It is not an easy quantity to determine especially in the case of the outer planets. The flattening can be obtained geometrically by using for example a double image micrometer in the focal plane of a large telescope or by the analysis of the isophotes of the image of the planet obtained from spacecraft photographs. It can be measured dynamically by observing the orbital perturbations of the inner satellites of the planet induced by its unsymmetrical mass distribution, calculating  $J_2$ , the quadrupole moment of the gravitational field and using the simple relationship between this quantity and the flattening  $\epsilon$ . Unfortunately if we take the fairly typical case of Uranus, the inner satellites Miranda, Ariel and Umbriel form a system with near commensurability of mean motions, a state of affairs that results in important mutual perturbations.

A. H. Cook of the Cavendish Laboratory, University of Cambridge reviews recent observations of  $\epsilon$  in the light of the new determinations of the spin periods of the planets and shows that some of the values obtained for  $\epsilon$  are implausible to say the least. His conclusions are presented in a recent edition of the *Monthly Notices of the Royal Astronomical Society* (**187**, 39P;

David W. Hughes is a Lecturer in the Department of Physics at the University of Sheffield.

1979).

For a planet in hydrostatic equilibrium the product  $C/Ma^2$ , where  $C$  is the moment of inertia about the polar axis,  $M$  is the mass and  $a$  is the radius, must be between specific limits. This quantity is 0.4 if the planet is of uniform density and drops to 0 for an extreme central condensation.

Unfortunately the present day values obtained for the dynamical properties of Uranus and Neptune are confusingly diverse. For Uranus, recent measurements of the spin period give two inconsistent values, one about 24 h and the other about 14.5 h. There are two values for Neptune as well, one about 22 h and the other about 18.5 h. Inconsistent values have been found for one or both planets for  $\epsilon$  and  $J_2$ .

Cook then considers all possible combinations of the observed parameters to see which if any can be rejected due to the physical unreality of the value of  $C/Ma$  so produced. The central pressures of Uranus and Neptune are comparable with those of the Earth, however the mean molecular weights of the material in these planets are less and the material is more compressible. Cook concludes that these planets have  $C/Ma$  values which are definitely greater than 0.25 and probably in excess of 0.3. On this basis both the values obtained for the geometrical flattening of Uranus, 0.028 and 0.01, are inadmissible. It is not possible to decide between the three  $J_2$  values of 0.00343, 0.005 and 0.012. For Neptune the  $\epsilon$  and  $J_2$  values both support the lower spin period of 18.5 h.

To resolve this sorry state of affairs the astronomical community must be stimulated into taking new observations. Unfortunately, as is so often the case, the best place to take these observations is outside the distorting atmosphere of planet Earth. □

## More spots before the eyes

from E. G. Richards

TREATMENT of *Escherichia coli* DNA with *EcoRI* restriction enzyme results in an estimated 500–600 fragments of DNA differing first in their molecular size and second in their base composition and sequence. If such a digest is examined by electrophoresis in agarose, a technique which separates DNA according to molecular size, a relatively featureless pattern is obtained, for the resolving power of the method is insufficient to resolve such a large number of components. How useful it would be, however, if this were possible.

Fischer and Lerman (*Cell* **16**, 191;

1979) have recently described a two-dimensional electrophoretic method which approaches this ideal. They start with the observation that a mixture of urea and formamide—both non-ionic substances—can denature DNA. That is to say, if the concentration of these denaturants is increased, a point is reached at which the DNA wholly or completely 'melts'. This critical concentration depends on the temperature, occurring at a lower concentration the higher the temperature, and also on the base composition and sequence, albeit in a complicated way.

In their first experiment Fischer and Lerman applied a sample of an *EcoRI* digest of  $\lambda$  phage DNA, containing six fragments, along the top of a slab polyacrylamide gel and subjected it to electrophoresis downwards. They had, however, arranged that the gel contained a gradient of concentration of urea and formamide in a direction perpendicular to the direction of migration. After electrophoresis they observed that in the part of the gel where denaturant concentration was low the six fragments were resolved according to molecular size and moved with a velocity almost independent of denaturant concentration. On the other hand, on the high-concentration side of the gel the components moved with a velocity reduced by a factor of 20 or 30 and remained near the top of the gel. At intermediate parts of the gel where the denaturant concentration took intermediate values, the components moved with intermediate velocities. The result was that the zone of DNA corresponding to each fragment was distorted into a sigmoidal curve resembling a 'melting curve'. Corresponding to each fragment there was a critical denaturant concentration at which the mobility fell to a low value and at which partial or complete denaturation took place. This critical concentration varied from one fragment to another and no doubt depended on the composition and sequence of the fragment. If the temperature at which the gel was maintained was reduced (from 60 °C to 45 °C) this critical concentration increased as expected. It may be noted that this simple description was slightly complicated for one or two fragments by the presence of more than one step in the 'melting curve', a phenomenon probably associated with the denaturation of separate domains of the DNA at different denaturant concentrations.

These observations are certainly entertaining but not of great apparent importance. This importance, however, is provided in the next and crucial stage of Fischer and Lerman's work when they rotated the denaturant gradient through 90° so that the concentration of urea and formamide increased in the direction of migration. They then ob-

served that each fragment set out on its passage down the gel with a velocity corresponding to its mobility in the native state. Sooner or later, however, each fragment reached a point in the gel at which it denatured and its mobility was reduced to a low value. At that point it came (almost) to a halt and was, as an added bonus, sharpened. A fragment came to a halt at a point which was not correlated with its size so that zones which were initially faster might be overtaken by larger and slower fragments if these were the more stable. The result was that the fragments were sorted out into the order of their stability rather than of their size.

The final step was then to perform an initial separation of the fragments in agarose to obtain a separation on the basis of size and then to lay a strip of the resulting agarose gel on top of a slab polyacrylamide gel and subject the separated fragments to electrophoresis in a direction perpendicular to the first and into a denaturant gradient. The result was six well separated spots distributed over the area of the slab. That is to say they were distributed in the two-dimensional electropherogram according to molecular size in one direction and according to stability in the other.

They then applied the method to an *EcoRI* digest of *E. coli* DNA and resolved up to 350 discernible spots. The authors suggest that further improvements in the sensitivity of detection might result in the appearance of more spots and point out that their method is capable of considerable further refinement. Meanwhile the significance of the method is demonstrated by the detection of four spots unique to a digest of lysogenic  $\lambda$  lysogen of *E. coli* which were not observed in uninfected *E. coli* DNA. Two of these corresponded in position to the spots obtained with  $\lambda$  phage DNA alone.

Meanwhile a rather similar trick was used by Creighton (*J. molec. Biol.* **128**, 235; 1979) in a study of protein denaturation. He subjected various proteins to electrophoresis perpendicular to a urea gradient in a slab polyacrylamide gel. He observed that although the mobility of these changed slowly as the concentration of denaturant was increased, possibly due to the effect of the urea on the viscosity of the interstitial fluid in which the proteins migrated, they underwent a more pronounced decrease in mobility at a critical concentration of denaturant at which denaturation took place. Creighton gives a mathematical appendix in which he analyses the distribution of protein in these sigmoid shaped zones

in terms of the mobilities and rates of denaturation and renaturation of the protein. Using this technique, he obtains further evidence of the all or none character of the denaturation of several proteins and in others of more complicated occurrences.

These two papers demonstrate again the remarkable versatility of gel electrophoresis without which life would be much less exciting to molecular biologists. It makes me wonder what the next jelly trick will be.  $\square$

## Pattern formation in chick limb bud

from Jonathan Slack

SOME biologists believe that a problem is as good as solved as soon as the right animal has been found with which to work, and in research on biological pattern formation the limb buds of the chick embryo have become a favourite system for study. In an organ such as this it is immediately clear that spatial patterning presents a problem separate from that of cell differentiation. This is because the limb consists of only a few cell types (muscle, cartilage, bone and connective tissue) but is built up of a complex quasi-periodic arrangement of these components in three dimensions, and the mechanism which brings about this arrangement demands explanation. A glimpse at the difficulties involved is provided however, by two recent papers in the *Journal of Embryology and Experimental Morphology*, which report attempts to test two of the most influential recent models (Wolpert, Tickle and Stampford *J. Embryol. exp. Morph.* **50**, 175; 1979; Summerbell *ibid.* 217; 1979).

The chick limb develops on the basis both of cell lineage and of intercellular interactions. The cells which form the myofibrils of the muscles are derived clonally from the somites, and the cells which form all the other tissues are derived from the lateral plate mesoderm (Chevallier, Kieny and Mauger *J. Embryol. exp. Morph.* **41**, 245; 1977). But the spatial pattern of both muscle and non-muscle elements seems to be controlled during outgrowth of the bud by additional mechanisms which act independently along each of the three morphogenetic axes (proximodistal, from the shoulder to the fingertips; anteroposterior, from thumb to little finger, and dorsoventral, from the upper to the lower surface of the limb).

Recent work on the formation of pattern in the proximodistal axis has been dominated by the progress zone model of Summerbell, Lewis and Wolpert (*Nature* **244**, 492; 1973). According to this model, the cells within 200–300  $\mu\text{m}$  of the tip of the limb bud constitute a labile region within which

some metabolic variable called the positional value rises continuously. Because the whole bud is growing, the rate of cell division being particularly high near the tip, cohorts of cells are being displaced continually from the progress zone, and when they leave the zone their positional value becomes frozen. The subsequent development of each cell then depends both on its ancestry (muscle or non-muscle) and on its positional value. This is the 'weak' form of the model. There is also a 'strong' form which asserts that the positional value of a cell in the progress zone is equal to the number of cell divisions through which it has passed since the commencement of outgrowth, and that the  $n$ th skeletal element in the final limb consists of a cohort of cells which all underwent  $n$  divisions in the progress zone.

The original experimental basis of this model involved grafting the tips of wing buds onto stumps of different ages. This led to a controversy between the laboratories of Wolpert in London (*Nature op. cit.*) and Kieny in Grenoble (Kieny and Patou Roux' *Arch.* **179**, 327; 1976; *J. Embryol. exp. Morph.* **41**, 137; 1977). The former group claimed that in these combinations each part developed according to its normal fate map (mosaic development) while the latter group claimed that deficiencies or excesses resulted in a reprogramming of the tissue and a re-establishment of the normal pattern (regulative development). When war between Britain and France seemed inevitable, the deadlock was broken by the dispatch of Summerbell to repeat the experiments in Grenoble. In the resulting concord (*J. Embryol. exp. Morph.* **41**, 137; 1977), both groups accepted that regulation occurs up to stage 22 but not later. At this stage of development the progress zone occupies a large proportion of the bud and so the existence of some interactions is not incompatible with the model.

This removed the strongest objection to the progress zone model, but all embryologists know that a demonstration of mosaic behaviour is not sufficient to prove a positive point because all theories of pattern formation involve a mosaic phase in between the time at which rudiments are first established and the time at which they become visibly differentiated. So a quite different type of experiment has been carried out in Wolpert's laboratory and the results are now reported (*J. Embryol. exp. Morph.* **50**, 175; 1979). Chick wing buds were subjected to a dose of X-irradiation sufficient to kill a certain proportion of their cells and the irradiated buds were allowed to develop after transplantation to healthy embryos. In the resulting limbs the proximal parts were reduced or absent

while the distal parts were well formed. The more intense the dose of radiation the greater the extent of the affected region. This is explained by arguing that the radiation kills a certain fraction of cells throughout the bud. Rudiments which are laid down shortly after irradiation are reduced in size for two reasons: first because a proportion of their cells has been killed, and second, because displacement from the progress zone is slowed down by the reduction in the proportion of dividing cells more distally. Because only the surviving cells proliferate, the progress zone eventually becomes repopulated by healthy cells and so the rudiments which leave the zone last, which are the most distal parts, develop to their normal size.

Does this work provide support for the progress zone model? It does indicate that the rudiments of the limb are laid down in proximodistal sequence, and that at a given stage the proximal part of the bud is a mosaic while the distal part is still labile, so to this extent it is compatible with the model. But it does not seem to me to have any bearing on the mechanism of generation of positional values in the rudiments. In particular it does not connect positional values with the cell cycle, for the sequence of divisions undergone by the surviving cells is presumed to be normal. So I think that it would be wrong to conclude that any evidence has been produced in favour of the strong form of the progress zone model.

Let us now turn our attention through 90° and consider the anteroposterior axis of the bud. The mechanism of pattern formation in this axis seems to be somewhat different from that in the long axis. There is a zone of tissue at the posterior edge of both the wing and the leg bud which is called the zone of polarising activity (ZPA). It is so called because when it is grafted to the anterior edge, it influences the surrounding tissues and causes them to form a second set of limb structures which are arranged in a relation of mirror symmetry to the original set (Saunders *Ann. N.Y. Acad. Sci.* **193**, 29; 1972). It has been suggested that the ZPA is the source of a morphogen that can diffuse into the other parts of the bud and is there destroyed. In the steady state situation the morphogen would be present as a gradient of concentration running from posterior to anterior and its function would be to evoke different pathways of cell differentiation at different levels (Tickle, Summerbell and Wolpert *Nature* **254**, 199; 1975). Some progress has been reported towards the chemical

isolation of the putative morphogen by McCabe and Parker (*Dev. Biol.* **45**, 349; 1975; *ibid* **54**, 297; 1976). Because this is probably the best analysed example of a morphogenetic gradient in the whole of embryology it was with some dismay that workers in the field listened to the talk given by Saunders at a meeting of the British Society of Developmental Biology in September 1976. For Saunders, who had discovered the ZPA in the first place, claimed at the meeting that it had no function at all in normal development. One argument in favour of this position was that buds whose ZPA had been removed at an early stage could go on to produce limb structures which, although often incomplete, were arranged in the normal manner (Fallon and Crosby *J. exp. Zool.* **193**, 449; 1975). The other was that tissue other than the ZPA, for example flank mesoderm or mesonephros, could show the same activity, indicating that the property is not very specific.

To counter these objections to the morphogen model, Summerbell has now reported an experiment designed to demonstrate the activity of the ZPA *in situ* without the need to graft it to an unnatural position (*J. Embryol. exp. Morph.* **50**, 217; 1979). This is done by inserting a small piece of tantalum foil into the bud at right angles to the anteroposterior axis so as to interrupt the transmission of any signal. In the limbs which develop after this operation structures are usually present only on one side of the barrier and when the barrier is placed near the centre of the bud the sequence of structures is truncated in the anteroposterior direction. The explanation for this is that the concentration of morphogen rises on the side of the barrier nearer the ZPA and falls on the side away from it. So a structure which is formed in response to a particular morphogen level will be deleted if its threshold lies in the concentration gap or will be shifted towards the barrier if it is still represented in the interrupted gradient. Summerbell produces computer simulations to demonstrate the reasonableness of this argument, and also describes a control experiment which shows that the gaps in the pattern are not simply the result of damage caused by insertion of the barrier. In many ways the logic and the results of this experiment are similar to those of constriction experiments on insect eggs (reviewed by Sander *Adv. Insect Physiol.* **12**, 125; 1976) which are also believed to indicate the existence of a morphogen gradient with a high point at the posterior end.

It would certainly be unfortunate if the ZPA did not have a role to play in normal development because it has now been detected in the limb buds of

mammals, reptiles and amphibia as well as birds and has found its way into a number of textbooks. But plausible though it is, it is difficult to see how the morphogen gradient model can be proved conclusively by macroscopic experiments alone, and whether the chick embryo limb bud will be capable of supporting the investigations down to the microscopic level of cellular physiology and biochemistry still remains to be seen. □

## A hundred years ago

ON the night of Sunday, May 25, loud bellowings were heard by the dwellers on the northern slopes of Etna. Towards the morning of the 26th these increased, and about midday a dense cloud of smoke was seen to issue from the side of the mountain below the great crater, apparently half way between Randazzo and Linguaglossa. This cloud increased, and on the 27th the mountain was rendered invisible, and an effect like that of an eclipse resulted. A rain of fine black ash, "like powdered emery," fell for miles around, and was so thick that Capo di Schiso could not be seen from Taormina, distance of two miles. This black rain continued all day accompanied by thundering noises from the mountain. No exact information could be procured concerning the position of the centre of disturbance, because no one could approach the new craters. During the night of the 27th the ashes continued to fall, and "huge fires could be seen looming through the black clouds"—no doubt the reflection of the molten lava on the smoke above it. It was reported in Piedemonte, a village on the north-east flanks of Etna, that three craters about a mile apart had opened at the points of a triangle, about six miles above Passo Pisciaro, a posting station nearly midway between Randazzo and Linguaglossa. Lava was said to be flowing in a valley to the north of the Val del Bove. On the 28th a great stream of lava was seen from Taormina to be descending the mountain in the direction of Randazzo, "while from the new craters great balls of fire were thrown high in the air, and burst into showers of fire like gigantic rockets, accompanied by thundering explosions." On May 29 the lava was still flowing, but the shower of ash was diminished. The facts, as above stated, were witnessed by an Englishman living in Taormina, 800 feet above the sea, at the north-eastern termination of the flanks of Etna, about fifteen geographical miles from the new craters.

## Weak interactions

Mary K. Gaillard

CERN, Geneva, Switzerland and LAPP, Annecy-le-Vieux, France

*Recent progress in weak interaction physics is reviewed. The status of the field and its prospects for the future are summarised.*

THE last decade has seen a revolution in the theory of weak interactions. Previously, a phenomenological prescription allowed the successful correlation of a large amount of data concerning nuclear  $\beta$ -decay and the decays of long lived elementary particles (muon, pion and the so-called strange particles) as well as neutrino-induced reactions and muon capture by nuclei. All these processes could be attributed to a simple interaction, the self-coupling of a single 'charged current'. However, the theory remained phenomenological in the sense that processes involving multiple weak transitions, or the interplay of weak and electromagnetic interactions, could not be calculated. In contrast, purely electromagnetic processes have long been understood; the theory permits the calculation of effects to any order in the electromagnetic coupling once the value of electric charge has been specified.

The new developments in weak interactions have resulted in the elaboration of a theory with a calculational power<sup>1</sup> equal to that of quantum electrodynamics. However, while measurements of electromagnetic processes have confirmed the theory to as many as six orders in the coupling constant, it is extremely difficult to test weak interaction theory beyond the lowest order. This is because the coupling is indeed weak, and higher order effects are generally beyond the limits of experimental precision. There are some measurable effects involving K-mesons which are forbidden at lowest order in the weak coupling and therefore measure directly the strength of higher order transitions. However, the interpretation of these phenomena is clouded by the effects of strong interactions.

Although they lack a laboratory for direct tests of the calculational power of the theory, most particle physicists are, nevertheless, convinced that they are on the right track. This is because the construction of the theory required the introduction of new interactions in the lowest order and of new elementary particles, neither of which had been observed. The spectacular confirmation of these predictions form the basis for the present confidence that there is at last a true theory of weak interactions. This article will deal with these new phenomena in so far as they are relevant to neutrino physics.

### Neutral currents

The weak transitions observed before 1973 could all be attributed to a mechanism involving the transmission of one unit of electric charge. This concept is best visualised in terms of pairs of elementary fermions such as the electronic leptons ( $e^-$ ,  $\nu_e$ ), the

muonic leptons ( $\mu^-$ ,  $\nu_\mu$ ), the lightest quarks (u, d), and the corresponding pairs of antifermions. The members of each pair differ by one unit of electric charge, and 'charged current' processes are those in which charge is exchanged between pairs as, for example, in neutrino induced inverse muon decay:

or in neutrino induced reactions involving hadrons, which are ascribed to a charge exchange reaction on quarks, the presumed constituents of hadrons:

The neutral current counterparts of reactions (1) and (2) would be, for example:

Reactions (3) and (4) were long believed to be absent at lowest order in the weak coupling. However, the occurrence of reaction (1) and its inverse implies that reaction (3) should also occur via a doubly weak transition

although at a much lower rate, since the rate for reaction (1) is already very small. The difficulty in constructing a real theory for weak interactions was that if one tried to calculate the rate for reaction (5) it turned out to be infinite.

Fig. 1 Inverse muon decay as mediated by a weakly coupled massive vector boson.

The problem is that one must sum over all intermediate ( $\mu^- \nu_e$ ) states in reaction (5), including those that violate energy conservation up to an amount allowed by the Heisenberg uncertainty relation  $\Delta E < \hbar/\tau$  where  $\tau$  is the interaction time. As far as we know from experimental results, the weak interaction is 'point-like'. That is, it has zero range and is instantaneous. That means that intermediate states of infinite energy contribute to reaction (5) with no damping, and the sum does not converge. This problem is avoided by introducing a finite space-time extension for the weak interaction, which is consistent with the data as long as the range introduced is shorter than distances which can be probed by present experiments. In quantum field theory the range of an interaction is governed by the mass of the mediator field: in quantum electrodynamics the mediator is the massless photon and hence the interaction range is infinite. For weak interactions the mediator must be sufficiently massive so that the effects of a non-zero range ( $\tau \sim r/c \sim \hbar/mc^2$ ) are beyond the reach of present experiments. For the conventional charged current interactions, Fig. 1, the presumed mediator is a charged vector boson  $W^\pm$ , and its mass must be greater than about  $20 \text{ GeV } c^{-2}$ .

The introduction of the charged bosons  $W^\pm$  suffices to damp high energy contributions ( $\Delta E \geq m_W c^2$ ) to the sum over intermediate states in reaction (5). At the same time we acquire new weak processes like the production of a pair of charged bosons via the exchange of a lepton, Fig. 2:

$$\nu_\mu + \bar{\nu}_\mu \rightarrow W^+ + W^- \quad (6)$$

While the  $W$ s must be so massive that their production would be difficult at present energies, we can consider higher order processes like

$$\nu_\mu + \bar{\nu}_\mu \rightarrow W^+ + W^- \rightarrow \nu_\mu + \bar{\nu}_\mu \quad (7)$$

again involving a sum over all energies of the intermediate  $W$ - $W$  system. Now a new difficulty arises. Experimental studies of weak processes have demonstrated that the intermediate boson must carry one unit of intrinsic angular momentum (spin), like the photon. However, unlike the photon the  $W$  is massive and therefore has three degrees of freedom instead of two. The amplitude for production of longitudinally polarised  $W$ s grows with energy like  $E/m_W c^2$ , so that the sum over intermediate states is not damped in spite of the space-time extension of the interaction in Fig. 2.

Fig. 2 Charged current muon exchange mechanism for  $\nu_\mu \bar{\nu}_\mu \rightarrow W^+ W^-$ .

We are left with a situation where a manageable theory of weak interactions cannot be constructed without introducing new processes which can interfere destructively with that of Fig. 2, so as to eliminate the high energy contributions to the sum in reaction (7). The simplest possibility<sup>2-4</sup>—and the one apparently chosen by nature—involves the introduction of a massive, electrically neutral spin-1 intermediate boson, the  $Z^0$ , which couples both to the elementary fermions (quarks and leptons) and also to the charged intermediate bosons. Then the mechanism of Fig. 3 can interfere destructively with that of Fig. 2, provided the coupling constants are suitably adjusted. Similar analyses of scattering processes involving charged fermions show that they

Fig. 3 Neutral current  $Z^0$  exchange diagram for  $\nu_\mu \bar{\nu}_\mu \rightarrow W^+ W^-$  which can cancel Fig. 2 to damp the reaction at high energy.

must also couple to the  $Z^0$ , but with a coupling strength that depends on their electric charge. This is because, for example, the process

$$e^+ + e^- \rightarrow W^+ + W^-$$

can also occur via photon exchange, Fig. 4a, and it is the sum of the three mechanisms of Fig. 4 which must cancel at high energies.

The above arguments mean that the couplings of the  $Z^0$  are tightly constrained in terms of the known charged current and electromagnetic couplings. The  $Z^0$  couples to a fermionic current which is an admixture of a part derivable from the charged current, involving only left-spinning fermions and right-spinning antifermions (that is a  $V-A$  current), and a part which is identical in structure to the (spin independent) electromagnetic current. The relative strengths of these two components depends on the relative strengths of the  $W^\pm$  coupling constant  $g$  and the electromagnetic charge  $e$ . Since low energy charged current reactions measure only the effective Fermi coupling constant,

$$\frac{G_F}{\sqrt{2}} = \frac{g^2}{8m_W^2} \approx 10^{-5}/m_p^2 \quad (8)$$

(where  $m_p$  is the mass of the proton), the theory is characterised by an unknown parameter which is commonly phrased in terms of a 'weak angle'  $\theta_w$ :

$$\sin \theta_w = e/g \quad (9)$$

The current coupled to the massive neutral boson  $Z^0$  is then decomposed according to

$$J^Z = J^{(V-A)} + \sin^2 \theta_w J^{\text{em}}, \quad (10)$$

where  $J^{\text{em}}$  is the electromagnetic current and  $J^{(V-A)}$  is the neutral counterpart of the charged currents. At low energies, exchange of a massive  $Z^0$  will appear as the point like self coupling of the current (10), generating transitions like (3) and (4).

Such processes were first observed<sup>5</sup> in 1973, only after their theoretical importance was realised, and provided an incentive for intensive searches. They had not been observed earlier because of the inherent experimental difficulties. Charged current transitions were extensively studied in decays long before neutrino experiments became feasible. A decay process which can occur via neutral currents, for example a nuclear transition with  $(e^+e^-)$  rather than  $(e\nu)$  emission, is completely masked by the much faster electromagnetic transitions. (This is not the case for strangeness-changing decays which we will discuss later; in fact it was the failure to observe neutral current transitions in strange particle decays which led most particle physicists to assume that only charge changing weak processes were present in nature.) After about 10 years of accelerator neutrino physics, neutral current reactions remained hidden. Neutrino scattering from electrons as in reactions (1) and (3) has a tiny cross-section compared with neutrino scattering from hadrons, and without the final state muon which signs the neutrino hadron scattering process (2), the analogous neutral current process (4) remained buried under neutron-induced background reactions.

Since their discovery<sup>5</sup> by the Gargamelle bubble chamber collaboration at CERN, neutrino-induced neutral current reactions have been studied in great detail<sup>6</sup>. The neutrino-hadron reactions which we have written in terms of the simple quark transitions (4) is translated in the laboratory to the very complex neutrino-nucleon interactions

$$\nu_\mu + N \rightarrow \nu_\mu + X \quad (11)$$

where  $N$  is a neutron or a proton and  $X$  is any allowed hadronic final state, from a single nucleon to a multi-particle system. Studies of a variety of final states have been carried out for both neutrino and anti-neutrino induced reactions. Experiments have also been performed to study the rarer  $\nu_\mu e^-$  and  $\bar{\nu}_\mu e^-$  elastic scattering processes, requiring the observation of an isolated electron track in a particle detector. In addition, the  $Z^0$  exchange contribution to electron-nucleon interactions has been observed<sup>7</sup> via its interference with the dominant photon exchange process. The cross-section for

$$e + N \rightarrow e + X \quad (12)$$

is found to depend on the polarisation of the incident electron, a parity violating effect which signals the contribution of a weak transition.

The simple fact that neutral current processes exist in nature does not provide evidence that cancellation mechanisms of the type described above are really at work. What is striking about the data is that they apparently confirm the precise spin- and charge-dependence of the neutral current coupling as prescribed by the requirement of such cancellations. In other words, each experiment can be analysed assuming the form of equation (10) for the neutral current, and that experiment will provide a determination of the weak angle  $\theta_w$ . The different processes studied yield values for  $\theta_w$  which are compatible with one another within the experimental uncertainties yielding an average value<sup>6</sup>  $\sin^2 \theta_w = 0.23 \pm 0.02$ .

The parameter  $\theta_w$  governs only the relative strengths of the components of the neutral weak current. There is a second measurable parameter which governs the overall coupling strength and is the neutral current analogue of the Fermi coupling constant, Equation (8), for charged current reactions. Constraints were obtained for the neutral current couplings by requiring cancellation of reactions at high energies where masses play no part. Those arguments only constrained the neutral current coupling relative to a particular combination of the  $W$  and photon couplings. The effective Fermi coupling for low energy neutral current reactions is therefore dependent on the  $Z^0$  mass; explicitly one finds

$$\frac{G_F^0}{\sqrt{2}} = \frac{g^2}{8 \cos^2 \theta_w m_Z^2} \quad (13)$$

However, the neutral boson mass  $m_Z$  is not completely arbitrary. The construction of a calculable theory is more delicate than our simple discussion suggests. To ensure that the required relationships among coupling constants remain stable against all higher order corrections, scalar bosons must also be introduced, and the masses of the vector bosons depend on the scalar (Higgs particle) content of the theory. The simplest possibility<sup>3,4</sup> for constructing a fully calculable theory containing three heavy vector bosons requires the introduction of a single scalar particle. In this case the vector boson masses satisfy the relation:

$$m_W^2 = m_Z^2 \cos^2 \theta_w \quad (14)$$

resulting in identical Fermi coupling strengths for charged and neutral current transitions:

$$G_F^0 = G_F \quad (15)$$

Measurements of the neutral current coupling strength satisfy this relation to within the experimental accuracy of about 5%.

To summarise: (1) neutrino experiments have revealed the existence of an interaction long thought to be absent: weak transitions with no exchange of electric charge. (2) The proper-

ties of this interaction are compatible with the requirement that higher order weak effects be calculable. (3) The experimental evidence strongly suggests that weak interactions have the simplest possible form which can satisfy the criterion of calculability.

## Charm and dileptons

We have already paired the elementary fermions according to

$$(e^-, \nu_e), (\mu^-, \nu_\mu), (u, d)$$

This is not quite correct. The up quark ( $u$ ) is actually paired with a superposition of the down quark ( $d$ ) and strange quark ( $s$ ),

$$(u, d_c); d_c \equiv \cos \theta_c d + \sin \theta_c s \quad (16)$$

where  $\theta_c$  is a phenomenological parameter known as the Cabibbo angle<sup>8</sup>. Equation (16) means that the sum of the squared amplitudes for, say, the semi-hadronic transitions

$$d \rightarrow u + e^- \bar{\nu}_e \quad (17)$$

$$s \rightarrow u + e^- \bar{\nu}_e \quad (18)$$

equals the squared amplitude for the purely leptonic transition

$$\mu^- \rightarrow \nu_\mu + e^- \bar{\nu}_e \quad (19)$$

which is the  $\mu$ -decay process. Reaction (17) is responsible for neutron and pion  $\beta$ -decay, while reaction (18) is responsible for the  $\beta$ -decay of strange particles. Comparison of the decay rates determines the Cabibbo angle:  $\sin \theta_c \approx 0.2$ . One of the most striking features of strange particle decays is the very strong suppression of neutral current transitions. For example, the neutral current process

$$K_L \rightarrow \mu^+ + \mu^- \quad (20)$$

is found to be suppressed relative to the charged current process

$$K^- \rightarrow \mu^- + \bar{\nu}_\mu \quad (21)$$

by a factor  $10^{-8}$  in the decay rate.

On the other hand, if we pursue the analysis described in the previous section, we see that the higher order quark-scattering process

$$\bar{d}s \rightarrow W^+ W^- \rightarrow \bar{d}s \text{ (or } \bar{s}d) \quad (22)$$

will have an infinite amplitude unless the mechanism of Fig. 5a for  $\bar{d}s \rightarrow W^+ W^-$  is cancelled by another mechanism, which one might assume to be the  $Z^0$  exchange mechanism of Fig. 5b. However, this would imply an effective neutral current Fermi coupling strength for strangeness changing processes as strong as that for charged current ones, and in particular the decay of reaction (20) would be as rapid as the decay (21). As this is in gross disagreement with the data, the only way to render the process (22) finite is to introduce yet another process. The simplest possibility is to introduce a new quark<sup>9</sup>  $c$ , with couplings to the  $d$  and  $s$  quarks such that the  $c$ -exchange diagram of Fig. 5c cancels the  $u$ -exchange diagram of Fig. 5a. This is achieved if the new quark, called a charmed quark, couples to the  $d, s$  combination which is orthogonal to the one coupled to  $u$ . Thus we introduce a new fermion doublet

$$(c, s_c); s_c \equiv \cos \theta_c s - \sin \theta_c d \quad (23)$$

To ensure that the delicate cancellations arranged for weak interactions are not destroyed by strong interaction effects, the charmed quarks must be subject to the same strong forces as the ordinary  $u, d$  and  $s$  quarks. This means that they should also form bound states. The fact that no charmed hadrons had been observed could be attributed to a higher mass for the charmed quarks and hence for their bound states. However, for this picture to be consistent with kaon data, the charmed quark mass could not be made arbitrarily high. The cancellation of the

Fig. 4 Mechanisms for  $e^+e^- \rightarrow W^+W^-$  which must interfere destructively at high energies in a calculable theory.

processes in Fig. 5a and c is only exact if the up and charmed quark masses are equal. Therefore, if  $m_c \gg m_u$ , the sum over intermediate  $W^+W^-$  states in reaction (22) will be damped only for energies  $E > m_c c^2$ . This is directly relevant to  $K$  decay; in the absence of a direct  $Z^0 \bar{s}d$  coupling, the decay (20) can still occur via higher order mechanisms such as

$$\bar{s}d \rightarrow W^+W^- \rightarrow \mu^+\mu^-$$

which will have an effective Fermi coupling determined by the charmed quark mass:

$$G_F^{\text{eff}} \sim \cos^2 \theta_c \sin^2 \theta_c G_F^2 m_c^2 \quad (24)$$

The tiny rate observed for the decay (20) is consistent<sup>10,11</sup> only with a charmed quark mass no greater than one or two  $\text{GeV } c^{-2}$ .

The startling discovery of the  $J/\psi$  particle with a mass of  $3.1 \text{ GeV } c^{-2}$  at Brookhaven<sup>12</sup> and at SLAC<sup>13</sup> in 1974 was immediately interpreted by several particle physicists as a charm-anticharm quark bound state. However, it took about two years before this identification was firmly established, and the study of the  $J/\psi$  family of  $\bar{c}c$  states led to considerable progress in the understanding of strong interaction dynamics. We describe here, however, how the weak couplings of charmed particles were studied, particularly in neutrino experiments. Once again these couplings are completely determined<sup>9,14</sup> by the requirement that the theory be calculable (cancellation between Fig. 5a and c), and they are characterised by two features: (1) the (c, s) coupling dominates the (c, d) coupling by a factor  $\cot \theta_c \approx 5$  in amplitude; (2) the charged current coupling is of the usual V-A type.

How are charmed particles produced in neutrino experiments? The nucleon is visualised as a system of bound quarks: three valence quarks which determine its quantum numbers (uud for the proton, ddu for the neutron) and quark-antiquark pairs which are referred to as the quark 'sea'. A neutrino incident on a nucleon can create a charmed quark via reactions like

$$\nu_\mu + d \rightarrow \mu^- + c \quad (25)$$

$$\nu_\mu + s \rightarrow \mu^- + c \quad (26)$$

where in reaction (25) the d can be a valence or a sea quark, but the strange quark in reaction (26) must come from the sea. The

weak interaction breaks up the nucleon, and the charmed quark picks up, say, a  $\bar{u}$  or  $\bar{d}$  antiquark from the hadronic debris to form a charmed D meson. The D meson will then decay weakly, mainly via the strangeness changing processes

$$c \rightarrow s + \{\mu^+ \nu_\mu \text{ or } e^+ \nu_e \text{ or } u \bar{d}\} \quad (27)$$

One therefore expects to find K mesons in the final state when a charmed meson has been produced. This prediction has been verified both in  $e^+e^-$  pair creation of D mesons<sup>15,16</sup> (via the electromagnetic process  $e^+e^- \rightarrow \gamma \rightarrow \bar{c}c$ ) and in neutrino production<sup>17,18</sup> of a single charmed particle. When the D decays into a system of only charged hadrons, it can be identified directly by the reconstruction of its mass ( $1.86 \text{ GeV } c^{-2}$ ) from the momenta of its decay products. If the D decays semi-leptonically some of its energy is taken by the unobserved neutrino. In this case the event is signed by an extra lepton in the final state. Such events were found<sup>6</sup> as expected to be characterised by an excess of kaons.

Even without identification of the hadrons in the final state, it is possible to verify the expectations (1) and (2) simply by studying dimuon events:

$$(\nu_\mu \text{ or } \bar{\nu}_\mu) + N \rightarrow \mu^- + \mu^+ + X \quad (28)$$

where X represents the final state hadronic system for which only the total energy is measured. The important elementary transitions contributing to dimuon events are reactions (25) and (26), followed by the decay

$$c \rightarrow s + \mu^+ + \nu_\mu \quad (29)$$

and antineutrino production of anticharm from the  $\bar{s}$  sea:

$$\bar{\nu}_\mu + \bar{s} \rightarrow \mu^+ + \bar{c} \rightarrow \bar{s} + \mu^- + \bar{\nu}_\mu$$

Antineutrinos can also produce  $\bar{c}$  from  $\bar{d}$  antiquarks in the nucleon's sea. However, the sea contribution is small, and scattering from s and  $\bar{s}$  is important only because it is favoured by the factor  $\cot \theta_c$  in amplitude. There can also be a charm-anticharm component of the quark sea, but ( $c\bar{c}$ ) pairs can be created only for a time  $\tau \sim \hbar/2m_c c^2$  which is small compared

Fig. 5 Mechanisms which might interfere so as to damp the strangeness changing reaction  $d + s \rightarrow W^+ + W^-$ ; a, Conventional charged current mechanism; b, neutral current coupling which is disallowed by K-decay data; c, charmed quark exchange.

with the interaction time unless the neutrino energy is well above the threshold for charm production.

Assuming that scattering from the charmed quark sea is unimportant, we expect the following characteristics for dimuon events.

(1) Because of the larger amplitude for scattering from an  $s$  or  $\bar{s}$  quark, the sea contribution is enhanced relative to that for ordinary single muon events. On average the sea quarks carry a smaller fraction of the nucleon momentum than ordinary quarks, so dimuon events should be characterised by a lower effective centre of mass energy for the scattered  $\mu^-c$  or  $\mu^+\bar{c}$  system. This effect should be most pronounced in  $\bar{\nu}_\mu$  induced events where sea quarks make the only contribution.

(2) The final state muon angular distribution depends on the relative spin alignments of the initial interacting fermions. The distribution is isotropic in the neutrino-quark centre of mass system if their spins are both aligned (right spinning) of both anti-aligned (left spinning) with their direction of motion. This is the case for the three processes (25), (26) and (30) if the coupling to charmed quarks are of the usual  $V-A$  type as predicted.

A few dimuon events, suggestive of charm production, were observed<sup>19</sup> even before the discovery of the  $J/\psi$ . By now several high statistics studies have been performed and they support<sup>6</sup> both the predictions (1) and (2) which verify, respectively, conditions (1) and (2) given previously.

## Beyond charm: multileptons

The addition of a charmed quark along with  $u, d$ , and  $s$  established a lepton-quark symmetry for weak interactions: for each lepton pair there is a corresponding quark pair. This symmetry is actually necessary<sup>20</sup> if the theory is to be fully calculable; otherwise infinite amplitudes are found to occur for processes like  $e^+e^- \rightarrow W^+W^-$  when higher order contributions are included. Therefore, the discovery<sup>21,22</sup> of the  $\tau$ -lepton and its associated neutrino led to the anticipation that still another quark pair ( $t, b$ ) should exist. This anticipation received partial confirmation in the discovery of the  $Y$  with a mass of  $9.4 \text{ GeV } c^{-2}$ , generally interpreted as a  $\bar{b}b$  bound state—leaving the  $t$  still to be discovered, presumably with a higher mass. Just as  $c$  couples preferentially to  $s$  in charged current transitions,  $t$  will couple preferentially to  $b$ , and it is not unlikely that  $b$  will decay more often to  $c$  than to  $u$ . Then cascade decays can generate spectacular multi-lepton events like

Unfortunately, the charged couplings of  $b$  and  $t$  quarks to the valence  $u$  and  $d$  quarks are constrained by other data to be very small, so that production cross-sections will not be large. Quadrimuon events have already been observed, but these data can be understood in terms of charm production accompanied by the Bremsstrahlung of a virtual photon, for example

It is hoped that beneath the background from this now 'conventional' source of multimuoons, a few events signalling still newer physics may be dug out.

## Prospects for weak interactions

Assuming that no experimental surprises will upset what now seems to be the steady confirmation of a true theory of the weak interactions, what is the future of the field?

(1) A crucial test of the theory which is still out of reach of present experimentation is the establishment of the actual existence of the postulated vector bosons,  $W^\pm$  and  $Z^0$ . If the theory is correct their masses are already known from the measured values of the weak angles  $\theta_w$ , the Fermi constant  $G_F$ , and the electric charge  $e$  through equations (8), (9) and (14). This gives

$$m_W = (77.8 \pm 3.4) \text{ GeV } c^{-2}, \quad m_Z = (88.7 \pm 2.7) \text{ GeV } c^{-2}$$

New facilities are being constructed at CERN and at Fermi Lab with the primary goal of producing and detecting these particles. A further important step would be their pair production by very high energy electron-positron colliding beams which would allow a probe of the WWZ coupling.

(2) The theory also requires the existence of one or more scalar particles, but little can be predicted about their masses or even their number, although recent speculations concerning the unification of strong, weak and electromagnetic interactions in terms of a single force (see below) place the mass of a scalar particle at about  $10 \text{ GeV } c^{-2}$ . Finding any scalar particle with the appropriate properties<sup>23</sup> would be an important confirmation of present theoretical ideas.

(3) Some theorists believe that detailed studies of hadrons containing the heavy  $b$  and  $t$  quarks may shed new light on the origin of CP violation, which so far has manifested itself only in the isolated neutral kaon system.

(4) The present theory contains an arbitrary parameter, the weak angle  $\theta_w$ . This parameter is indeterminate except within the context of an enlarged theory containing new couplings and new vector bosons. Much theoretical effort is being devoted to the construction of a theory which not only determines  $\theta_w$ , but describes the strong, weak and electromagnetic forces in terms of a unique coupling constant. There has been considerable progress in this direction, but the experimental predictions which could test such a theory are up to now extremely limited, and even higher energies do not promise much more. The most exciting possibility at present is that the proton may be unstable and have a lifetime which is accessible to experimental measurement.

(5) The outstanding problem is an almost total lack of understanding of the fermion spectrum. How many fermion pairs are there? Why are their masses so disparate? Are neutrino masses absolutely zero? Why do quarks form weakly interacting pairs according to particular superpositions of quark states? Some of these questions have been partially considered by the attempts to unify forces discussed above. Some of their answers may also be related to the scalar particle content of the theory. But the general theoretical stalemate with respect to the elementary fermions suggests most persistently that further surprises may be in store.

## Mid-Mesozoic closure of Permo-Triassic Tethys and its implications

A. M. Celâl Şengör

Department of Geological Sciences, State University of New York at Albany, Albany, New York 12222

*Data from the northern Tethyan domain indicate that Permo-Triassic Palaeo-Tethys closed between the late Triassic and the mid-Jurassic. This closure was caused by the collision with Laurasia of a Cimmerian continent rifted away from northern Gondwanaland during the Triassic. The Neo-Tethys may have opened partly as a back-arc basin over the Palaeo-Tethyan subduction zone and rotation of the Cimmerian continent may have been partially responsible for mid-Mesozoic block-faulting in extra-Alpine central Europe.*

HSÜ<sup>1,2</sup> suggested that the Tethyan Ocean, contemporaneous with the latest Palaeozoic-early Triassic Pangaea<sup>3-5</sup> was obliterated mainly during the Jurassic along a suture zone that must lie north of the late Mesozoic-Cenozoic sutures of the Tethyan orogenic system. This is an attractive hypothesis because all the late Mesozoic-Cenozoic sutures within the Tethyan Orogen represent oceans (hereafter Neo-Tethys) that opened during the Triassic and later<sup>6</sup> (Fig. 1). They cannot therefore mark the site of the latest Palaeozoic-early Triassic Tethys (hereafter Palaeo-Tethys; Tethys 1 of Dewey *et al.*<sup>5</sup>). I review evidence here from the Alpine/Himalayan orogenic system for the existence and mid-Mesozoic closure of Palaeo-Tethys and discuss some tectonic implications of this event.

### Regional review

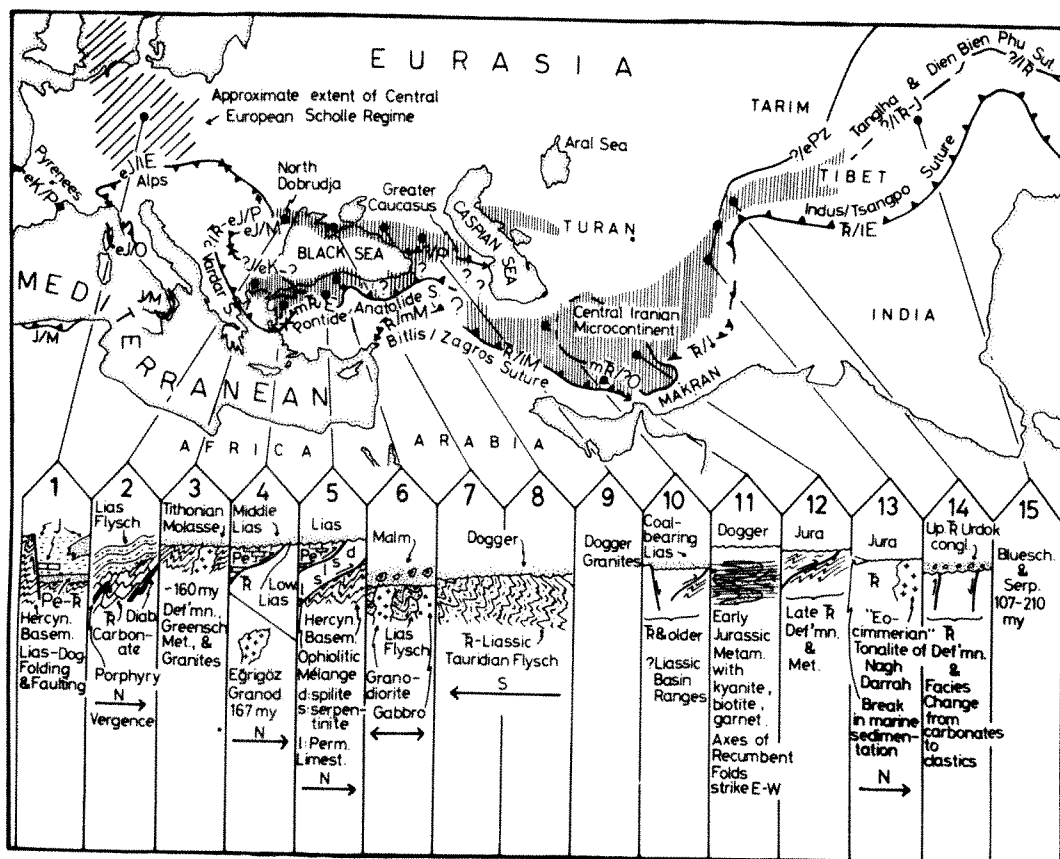

The existence of Palaeo-Tethys is implied by the observation that when the continents around the Atlantic and Indian Oceans are restored to their positions before the break-up of Permo-Triassic Pangaea<sup>3-8</sup>, a large, westward narrowing triangular area appears between Laurasia and Gondwanaland. Figure 1 shows that all of the Alpine-age sutures south and west of Dobrudja-Crimea-Greater Caucasus represent oceans that opened during the Triassic or later (Pyrenees: early Cretaceous<sup>9</sup>; Alps/Apenines: early Jurassic<sup>10</sup>; Carpathians/Vardar Ocean: late Triassic and/or early Jurassic<sup>5</sup>; Pontide/Anatolide Ocean: mid-Triassic<sup>11,12</sup>; Bitlis/Zagros Ocean: Triassic<sup>13</sup>; North Makran/Afghanistan and Indus/Tsangpo Oceans: Triassic<sup>14</sup>). These Neo-Tethyan oceans mostly ruptured northern Gondwanaland. As far west as the Balkans they cut terrains characterised by Pan African/Baikalian or older basement, and from the Balkans westwards they cut Hercynian basement (ref. 15, Fig. 6). Evidence, both from Atlantic and Indian Ocean magnetic anomaly

lineations<sup>5,8</sup> and from palaeogeographic analyses of the peri-Tethyan domain<sup>6,15</sup> shows that the Permo-Triassic Palaeo-Tethys must have lain north of the Alpine sutures, separating late Palaeozoic Laurasia from late Palaeozoic Gondwanaland.

No pre-Triassic ophiolite complexes have been confirmed within the Alpine System<sup>1-5</sup> and therefore it has been difficult to locate the site of the closure of Palaeo-Tethys. Because of the sparsity of ophiolites I use here a variety of criteria such as compressional deformation, Barrovian metamorphism, calc-alkaline magmatism, rapid emergence and flysch/molasse facies sedimentation collectively to identify a zone within which I suggest the Palaeo-Tethyan suture is located. One of the chief reasons why the suture zone has so far gone undetected is that it lay very close to the northern margin of Neo-Tethys and the very intense deformation associated with the closure of that complex ocean has largely overprinted the signature of the earlier collision. Figure 1 shows areas thought to have been affected by the deformation associated with the closure of Palaeo-Tethys. This area is widest where terminal Alpine collision has not yet occurred (north of Makran), an observation that supports the view that the Alpine collisions have very strongly overprinted the earlier structures.

The westernmost places where the effects of early to mid-Mesozoic convergent plate margin activity can be seen are the peri-Rhodopean Belt in the northern Aegean (Fig. 1, loc. 3; refs 16, 17) and in North Dobrudja (Fig. 1, loc. 2; ref. 18 and the bibliography therein). The precise geometry of the mid-Mesozoic deformation in the peri-Rhodopean Belt is not well-understood, but Kockel *et al.*<sup>15</sup> have reported intense folding, greenschist metamorphism and granite intrusion sometime during the Dogger-Malm transition. The deformed assemblage is overlain by Tithonian molasse<sup>17</sup> indicating that here deformation had long ceased when the Eo-Hellenic tectonism began in the sub-Pelagonian area in post-Tithonian times<sup>17</sup>. Whereas the peri-Rhodopean deformation may be related to the closure of Palaeo-Tethys, the Eo-Hellenic ophiolite obduction is clearly pre-collision Neo-Tethyan. In North Dobrudja the geometry is much clearer and involves a north-vergent, imbricated and folded series that includes Alpine-type Triassic and possibly early Liassic carbonates and flysch-facies deposits (Nalbantian Flysch). Porphyry and diabase dykes were intruded during the Trias. Middle Lias is unconformable on this deformed and intruded assemblage. The entire deformed package, making up the Tulcea Zone, is overridden from the south along a major thrust<sup>18</sup> by the Macin Zone that was deformed largely during the Palaeozoic. Because the Baikalian (late Proterozoic) Moesian Platform with its gently deformed Phanerozoic cover is now

**Fig. 1** The approximate area (vertically ruled) affected by mid-Mesozoic orogeny and thought to have coincided roughly with the present extent of the rocks representing the Cimmerian continent(s), the collision of which with Laurasia is believed to have caused the mid-Mesozoic orogeny. Localities for which stratigraphic, structural and petrologic data are given in the columns (1–15). The bold lines are sutures (dashed where inferred). Polarity information, where available, is indicated by black teeth on the overriding continent. Ages on the sutures are ages of ocean opening and closing for the segments limited by arrowheads and abbreviated as follows: Pz, Palaeozoic; T, Triassic; J, Jurassic; K, Cretaceous; P, Palaeocene; E, Eocene; O, Oligocene; M, Miocene; ↓, active subduction; e, early; m, medial; l, late. In the columns Pe denotes Permian. Horizontal zig-zag lines are unconformities.

located between North Dobrudja and the peri-Rhodopean Belt, relationships between these provinces are not clear.

Eastwards, along the strike from Dobrudja, the Triassic to Liassic Tauridian Flysch in the Crimean Mountains (Fig. 1, loc. 7; refs 19, 20) exhibits a strong, south-vergent fold and imbricated thrust structure<sup>21</sup> unconformably overlain by Dogger sandstones. The same stratigraphy and structural picture is exhibited in the basement of the northern slope of the West Kubanian foredeep (Fig. 1, loc. 8; ref. 22), where a thick Middle–Upper Triassic flysch with volcanics has been folded during the Trias–Lias transition. Although similar lithologies of the same age have been encountered in deep drill-holes farther east (eastern shore of the Caspian Sea, Fig. 1, ref. 19), the structural picture there is not known. A strip is thus roughly defined north of the Black Sea characterised by deformed Triassic–Liassic flysch with volcanoclastic components and by diabase and porphyry intrusions.

Parallel with this strip, the southern shores of the Black Sea exhibit stronger, predominantly north-vergent mid-Mesozoic orogenic activity (at this time the Black Sea had not opened and its southern shores may have been much closer to the strip defined above, depending on the position of the Moesian Platform at the time). Around Balya in western Turkey (Fig. 1, loc. 4, ref. 23) Radelli mapped Permian limestones lying with thrust contact on Triassic and Lower Liassic rocks. The thrusts are truncated by an unconformity over which Middle Lias was deposited. Just east of Balya, north of Simav, the Eğrigöz granodiorite gives a Rb–Sr whole-rock age of  $167 \pm 14$  Myr (ref. 24). In the Karagöl region, north of Ankara (Fig. 1, loc. 5; ref. 25), the same Permian limestones are overthrust onto an ophiolitic mélange containing spilites, serpentinites and blocks of the Permian limestones; this package, in turn, is seen in thrust contact on Hercynian basement and all are unconformably overlain by Lias. Other than the northeastern Pontide ophiolites of northeastern Turkey (see below), the suspected pre-Mesozoic ophiolite slivers of Mashad<sup>1</sup>, northern Iran, and the serpen-

tinities along the Tanglha suture in Tibet (Fig. 1, loc. 15), this ophiolitic assemblage is the only occurrence I know that may represent Palaeo-Tethyan ocean floor material. Farther north-east, around the towns of Küre, Inebolu and Devrekâni (Fig. 1, loc. 6; ref. 26), dioritic, granodioritic and gabbroic plutons have been mapped to intrude Liassic flysch. Pebbles of these intrusives are encountered in the basal conglomerate of transgressive Malm sequences. Dogger intrusions of 'granitic' composition are also known from the Greater Caucasus (Fig. 1, loc. 9; ref. 22). Blumenthal<sup>27</sup> has pointed out that the northernmost ophiolite outcrops in the northeastern Pontides in Turkey are of pre-Liassic age.

In central Iran there is abundant evidence for late Triassic–early Jurassic convergent plate–margin activity and Stöcklin has emphasised the importance of the 'cimmerian' movements in this sector of what he has designated the Central Domain, where (Fig. 1, loc. 10; refs 28, 29) late Triassic block-faulting is generally associated with thrusting and intense local folding. This deformation has often been cited as evidence for the rifting of central Iran from Arabia<sup>5,29</sup>. However, the following observations indicate plate convergence: (1) the existence of strongly tectonised regions displaying Barrovian metamorphism (kyanite–biotite–garnet assemblages), accompanying deformation characterised by recumbent similar folding with a strong axial plane schistosity striking east–west in the southeastern extremity of the Sanandaj–Sirjan Zone (Fig. 1, loc. 11; refs 30, 31); (2) strong folding, thrusting and metamorphism of the basement of the Lut Block (central Iranian microcontinent of Takin<sup>32</sup>) (Fig. 1, loc. 12; ref. 28). All of these events took place between the late Triassic and the early Jurassic<sup>28,30,31</sup>. The coexistence of strong compressional deformation and the inferred block-faulting in central Iran during the late Triassic times may be explained in two different ways. First, the area of central Iran may have felt simultaneously the effects of the opening of the Bitlis/Zagros Ocean (a part of Neo-Tethys) and the closing of Palaeo-Tethys. A modern example of a similar association is

the Aegean region<sup>33,34</sup>. Conversely, a basin-and-range regime may have existed in central Iran associated with complications of the convergent plate-margin regime related to the closing of Palaeo-Tethys. Similar complications are observed in the Neogene-Quaternary tectonics of the western US<sup>35</sup>. Ultramafic rocks occurring in ?Carboniferous slates near Mashad, in northern Iran, were interpreted by Hsü<sup>1</sup> as possible representatives of the floor of Palaeo-Tethys.

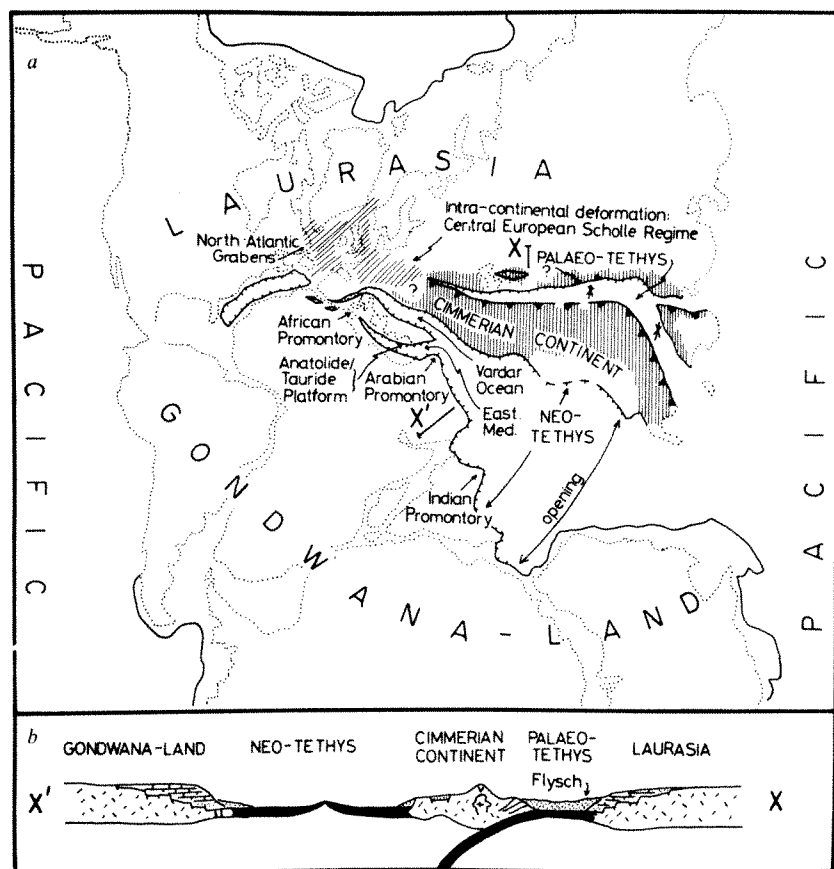

Although the data are sparse and imprecise, in Afghanistan and Pakistan the Triassic-Jurassic transition is characterised by tectonism<sup>36</sup>, a break in marine sedimentation<sup>37</sup> and intrusion of calc-alkaline igneous material such as Salang and Doab granites of western Hindu Kush Mountains (isotopic age:  $210 \pm 10$  Myr; ref. 38). In western Hindu Kush, tectonism is characterised by a strong, north-vergent nappe tectonics of intra-Jurassic age<sup>38</sup> (Fig. 1, loc. 13). Farther east, in the Pamirs and the Karakorum (Fig. 1, loc. 14; refs 28, 39, 40) the late Triassic-early Jurassic orogenic activity is better documented: in the Pamirs the deformation was accompanied by the intrusion of calc-alkaline plutons and by a sharp facies change from shelf carbonates to a coarse clastic facies. In the Karakorum this latter facies is represented by the 'orogenic' Urdok Conglomerate which is the only coarse clastic sediment recognised in the Palaeozoic-early Mesozoic section<sup>40</sup>.

Eastwards, the mid-Mesozoic zone of deformation enters the Tibetan Plateau, the geology of which is little known. Chang and Zeng<sup>41</sup> indicate that there is a Mesozoic arc suture along the Tanglha Mountains (Fig. 1, loc. 15) with serpentinites and blueschists; isotopic ages along the Tanglha Mountains range from 210 to 107 Myr (ref. 41). Alternatively, Sengör and Kidd<sup>42</sup> interpret the entire pre-Jurassic basement of Tibet as a giant accretionary mélange prism, first hit by a continent during the Himalayan collision. The Tanglha suture seems to continue along strike into the late Triassic Dien Bien Phu suture in southeastern Asia (Fig. 1; ref. 43). If the Tanglha suture represents a mid-Mesozoic continental collision (or arc-continent collision), we may continue the zone of mid-Mesozoic

orogeny into Tibet as a suture zone. Conversely, if the hypothesis of Sengör and Kidd<sup>42</sup> is correct, then the Palaeo-Tethyan suture must have joined, from both sides, the large accretionary prism of Tibet, much as the present accretionary prism of Makran<sup>44</sup> links the Zagros and Indus-Tsangpo sutures. Palaeobiogeographic data (summarised in ref. 45) indicate that the welding of southern and northern Tibet occurred sometime between Permian and Jurassic.

## Discussion and implications

The evidence reviewed above, when coupled with the marine magnetic and palaeogeographic arguments for the existence of Palaeo-Tethys, may be interpreted in terms of a late Triassic to medial Jurassic closure of this ocean. This closure occurred between Eurasia and the continental fragment(s) rifted from the northern side of Gondwanaland. Figure 2a shows the simplest possible interpretation of this continental fragment which I call here the Cimmerian continent after the Cimmerian Mountains that comprise the Macin Mountains, the Serpent Island and the Crimean Mountains. Clearly the Cimmerian continent may have had a very different geometry and have been composed of more than one fragment. The lack of precise simultaneity or of a regular age progression along the zone of mid-Mesozoic orogeny support the concept of a segmented Cimmerian continental archipelago and the apparent interruption in the zone of mid-Mesozoic deformation in northwestern Iran, the circum-central Iranian microcontinent suture (Fig. 1), and the evidence that Tibet may be characterised during this interval as a large accretionary prism indicate where such possible discontinuities may have been located. Neo-Tethys has also similarly closed by independent fragments of Gondwanaland. The pre-Alpine internal structure and possible width of the Cimmerian continent(s) are particularly difficult to assess because of the very strong Alpine overprint. In all areas where the mid-Mesozoic closure of Palaeo-Tethys caused deformation (Fig. 1) there has also been both intense Alpine orogenic deformation

**Fig. 2** a, Latest Triassic-early Jurassic reconstruction of Pangaea and Tethys (base map from ref. 54) showing the simplest possible interpretation of the internal geometry of the Tethyan realm. All the elements shown, particularly the poorly-defined Cimmerian continent, could have had different and probably more complex geometries. Vertically ruled area corresponds to that in Fig. 1, that is it represents the regions affected by mid-Mesozoic orogeny. Here the width of the Cimmerian continent is purely hypothetical and may be as much as three times too large. Obliquely ruled areas are regions of complex intracontinental extension inferred to have been partially related to the closure of Palaeo-Tethys. Lines with black triangles are subduction zones with the triangles on the upper plate. Lines with short hachures represent passive continental margins (no fit is intended between the southern and northern shores of Neo-Tethys due to lack of data). Dotted lines are the present continental shore-lines put in for reference. XX' indicates the location of the cross-section shown in b. b, A highly schematised cross-section showing the major elements considered in the text. Black denotes oceanic and short, irregular lines denote continental crust, +, Calc-alkaline intrusive; v, calc-alkaline volcanic rock.

and exceedingly complex post-collisional foreland deformation<sup>33,34,42,46,47</sup>. These later events and the associated extensive volcanics and Neogene sedimentary cover seem to have obliterated or hidden the pre-Alpine characters of the Cimmerian continent(s) beyond any reasonable hope of coherent synthesis.

Because of the very fragmental and imprecise nature of the data, particularly from Iran eastwards, it is difficult to interpret the polarity(s) of Palaeo-Tethyan subduction zone(s). The location of relatively less deformed and largely unmetamorphosed flysch/molasse sequences to the north of the strongly deformed, metamorphosed and intruded, more 'internide-looking' predominantly north-vergent orogenic terrains as far east as Afghanistan may indicate that at least in this sector the Palaeo-Tethyan orogen was probably north-facing with a south-dipping subduction zone. In Tibet, if the regions north of the Tanglha Mountains are composed of late Palaeozoic-early Mesozoic accretionary mélange material, the subduction zone may have been dipping northward; but here data are so sparse that the question is open.

If the above proposed scheme is approximately correct, then it has interesting implications for two problems outside the Palaeo-Tethyan area. One is the complex, intracontinental zone of extension in extra-Alpine central and northwestern Europe (Fig. 1, loc. 1; refs 48-50). This broad zone of extension, characterised by a complicated pattern of block faulting (Schollen), became active during Liassic (?earlier) time and accelerated during the Malm. I suggest that this predominantly intracontinental extensional regime was possibly caused by the closure of wedge-shaped Palaeo-Tethys. If the pole of rotation of the Cimmerian continent(s) was located somewhere between North Dobrudja and Germany, as suggested by the observation that no early to mid-Mesozoic orogenic activity is known in Europe west of North Dobrudja, then the convergent plate boundary system, if not joined near the pole by other plate boundaries, must have become extensional once it crossed the pole. This extension should have increased away from the pole; indeed the early to mid-Mesozoic extension in the North Sea-North Atlantic regions was far more intense than it was in central Europe<sup>50</sup>. The broad distribution of the associated strain may have been because extension was taking place in continental lithosphere and was following Permo-Triassic intracontinental grabens and shear zones<sup>51</sup>. It may, however, prove impossible to distinguish between extension caused by the initial

opening of the Atlantic and that related to the hinging of Palaeo-Tethys.

The second problem is related to the opening of Neo-Tethys. I suggest that if the Cimmerian continent or substantial segments thereof were sufficiently narrow, that is if they were essentially island arcs, the Triassic opening of Neo-Tethys may be interpreted as the opening of a series of back-arc basins or at least initiated by back-arc spreading processes (Fig. 2b). McKenzie and Weiss<sup>52</sup> have pointed out that it seems particularly difficult to initiate constructive plate margins. They suggested that back-arc spreading may be the triggering mechanism for initiating major oceans, as back-arc spreading and seafloor spreading in major oceans seem to be the same process (see appendix in ref. 53). Although their main example, the South Atlantic, was unfortunate, the idea may be applicable, at least to parts of Neo-Tethys.

## Conclusions

Palaeo-Tethys that must have existed during the Permo-Triassic between Laurasia and Gondwanaland closed during the late Triassic-mid-Jurassic possibly along one or more suture zones located within the zone of mid-Mesozoic orogeny shown in Fig. 1. As a result of very strong Alpine overprinting associated with the latest Mesozoic-Cenozoic demise of Neo-Tethys and because of the sparsity of data neither the precise geometry of the suture(s) nor that of the continent(s) that collided with Laurasia to close Palaeo-Tethys can be reconstructed. However, my interpretation permits a satisfactory explanation of a number of phenomena, notably the following: (1) The mid-Mesozoic convergent plate-margin activity in a relatively narrow band stretching from Rhodope and North Dobrudja to southeastern Asia and the observation that the Alpine-Himalayan sutures represent oceans opened not before the Triassic. (2) The mid-Mesozoic extensional regime in extra-Alpine central Europe which may be viewed as a partial consequence of the convergent plate-margin activity in the Palaeo-Tethyan realm. (3) The opening of Neo-Tethys which may be considered, at least in part, to be an example of back-arc spreading associated with the subduction of the Palaeo-Tethyan ocean floor.

I thank Professor Kenneth J. Hsü for stimulating my interest in the Palaeo-Tethys, Professors Kevin Burke and Clark Burchfiel for helpful comments.

# Sand on the southern Mediterranean Ridge: proximal basement and distal African–Nile provenance

Daniel Jean Stanley & Harrison Sheng

Division of Sedimentology, Smithsonian Institution, Washington, D.C. 20560

Mahmoud M. Kholief

Egyptian Petroleum Research Institute, Cairo, Egypt

*Petrographic analysis of Quaternary terrigenous sand layers in eastern Mediterranean cores reveals distinct mineralogical differences between the Egyptian Shelf–Nile Cone region and the southern part of the Mediterranean Ridge. A compositionally and texturally immature suite in Ridge cores, mixed with a Nile-derived assemblage, identifies a fresh non-recycled mineral component derived from proximal igneous and metamorphic surface or near-surface exposures, probably in the south-central Ridge area rather than from distal African sources. The presence of such basement terrains would be consistent with a compressive thrust-belt origin for this part of the Mediterranean Ridge.*

THE Mediterranean Ridge, the broad arcuate swell in the eastern Mediterranean extending from the Ionian Sea to the eastern Levantine Basin, constitutes a distinct topographic and tectono-stratigraphic province between the seismically active southern European and more stable North African margins. The characteristic hummocky ridge-and-swell topography of the Ridge is the surface expression of what appears in seismic profiles as a folded and faulted sediment complex<sup>1,2</sup>. The contact between deformed sedimentary units of the southern part of the Ridge and the more gently stratified, Plio-Quaternary series forming the western Nile Cone tends to be well-defined<sup>3</sup> and delineates the northwestern margin of the Herodotus Basin plain (Fig. 1). A mid-oceanic ridge origin<sup>4</sup> can be ruled out for the Mediterranean Ridge, but there is considerable diversity of opinion as to the structural and stratigraphic configuration<sup>5–7</sup>. The various hypotheses pertaining to the geological development of this feature are reviewed by Finetti<sup>8</sup> and Stride *et al.*<sup>9</sup>.

All the schemes invoke important large-scale tectonic displacement in the late Tertiary to the present, and one would expect that evidence of these geologically recent events should be recorded in sedimentary sequences deposited in this area. This article focuses on the provenance of terrigenous sand layers of Pleistocene age on the southern part of the Ridge at the approximate midpoint between the more obvious potential sources of sediment: Nile Delta, Crete, Cyprus and the Eratosthenes Seamount. This sector has more specifically been termed the Hellenic Outer Ridge<sup>9</sup>. Pleistocene and possibly Upper Pliocene core sections recovered in this part of the Ridge in 1970 at DSDP Site 130 (Fig. 1) have been interpreted as distal Nile Cone deposits which were uplifted <1 Myr ago and subsequently deformed<sup>2</sup>. Arguments in support of this scheme are based partly on regional correlation of sub-bottom reflectors of probable Messinian and post-Miocene age, but more specifically on mineralogical comparisons between DSDP Sites 130 and 131 at the base of the Nile Cone (ref. 2, p 735 and 1033;

ref. 10) and on the pollen content in Pleistocene samples at Site 130<sup>11</sup>. These studies all emphasise the North African, largely Nile, affinity of the southern Ridge deposits. The difference in relative percentages of the dominant heavy minerals (primarily an amphibole–pyroxene–epidote–opaque mineral suite) between Nile Cone and Ridge samples is attributed by Ryan and others<sup>2</sup> to differences in grain size and to changes of source terrain drained by the Nile River during the Quaternary.

This study considers heavy and light minerals from terrigenous sand layers, mostly turbidites, in DSDP Site 130 and 131 cores and in Pillsbury 6508 and 6510 and Vema 10 piston and gravity cores on the outer Egyptian Shelf, Nile Cone and Herodotus Basin plain, and shallower marine palimpsest deposits in Chain 119 grab samples on the inner to middle Egyptian Shelf in front of the Nile Delta (Fig. 1). Observed regional differences indicate a more complicated provenance-dispersal of Pleistocene sediment on the southern part of the Mediterranean Ridge than previously envisioned.

## Petrographic observations

Most Pleistocene sand layers in the Nile Cone and the Mediterranean Ridge core sections are of bioclastic origin<sup>12</sup>, and our investigation considers only terrigenous or mixed terrigenous–bioclastic layers. Of about 225 sand layers sampled in the cores shown in Fig. 1, only 47 examined had a sufficiently heavy mineral content for grain count (Table 1). Data are based on the calculated 62 to 250 µm heavy mineral fraction of each layer to minimise size-sorting effects. Heavy fractions were separated by the standard heavy liquid method and 300 grains were identified. The listed data shows that the study area occupies a province dominated by pyroxenes, amphiboles, epidotes and opaque minerals; these four account for more than 90% of the total heavy minerals in most samples, as was indicated in earlier investigations<sup>2,10,13,14</sup>.

Vertical changes were observed in some cores (Table 1): for example, in DSDP Site 131 from the lower Nile Cone, there is a slight downcore increase in pyroxenes and epidotes and an increase in amphiboles; in Pillsbury core 6510–18 on the outer Egyptian Shelf, there is a slight downcore increase in pyroxenes and amphiboles, and a more random change in epidote content. Regional–spatial changes are more apparent and include a general decrease in the relative percentage of opaque minerals between the outer edge of the shelf and distal Nile Cone stations. Overall, the Nile Cone samples in grabs, short piston and gravity cores and in DSDP Site 131 are genetically related to the same general assemblage as the Nile River valley, Nile Delta and coastal sequences<sup>13–17</sup>.

The most pronounced changes in heavy mineral assemblages occur between the inner and outer Egyptian Shelf and between the base of the Nile Cone and the southern part of the Mediterranean Ridge. These regional distinctions become evident when considering the ranges of relative percentages of minerals in the

**Fig. 1** Chart of the southeastern Mediterranean showing sample station locations on the Egyptian Shelf (EG), Nile Cone and southern part of the Mediterranean Ridge. ES, Eratosthenes Seamount; EBP, Eratosthenes Basin plain. Numbers refer to core and grab sample station and, in parentheses, the relative percentage of amphiboles in the non-opaque heavy mineral assemblage (data from Table 1). Note increased amphibole content in Ridge samples. ●, Chain 119; ○, Pillsbury 6508; ■, Pillsbury 6510; △, Vema 10; ▼, DSDP Leg 13.

three major topographic sectors of the study area (Table 1):

(A) On the Egyptian Shelf (10 stations): clinopyroxenes (8.5–62.8), orthopyroxenes (0.0–7.9), amphiboles (5.0–33.3), epidotes (6.5–37.0), garnets (0.0–46.3), zircon–tantalum–rutile, or ZTR (0.0–6.5), apatite (0.0–1.6), opaques (23.0–70.0).

(B) On the Nile Cone proper (nine stations): clinopyroxenes (12.9–46.5); orthopyroxenes (0.0–3.3); amphiboles (11.9–40.8); epidotes (4.8–30.6); garnets (0.0–2.5); ZTR (0.0–4.7); apatite (0.0–1.6); opaques (11.0–60.0).

(C) On the southern Mediterranean Ridge (two stations): clinopyroxenes (10.0–17.3); orthopyroxenes (0.4–2.0); amphiboles (43.4–65.8); epidotes (8.5–26.5); garnets (0.4–3.6); ZTR (0.4–3.6); apatite (1.6–2.2); opaques (47.0–68.0).

Nile Cone (B) samples display a narrower range in relative percentage and smaller core-to-core differences (particularly clino- and orthopyroxenes and garnets) than the Egyptian Shelf (A) samples. The southern Ridge (C) samples (DSDP Site 130 and Pillsbury 6510–17) are distinguished from Nile Cone–Herodotus Basin plain (B) samples by enhanced proportions of amphiboles and lower percentages of pyroxenes as noted earlier by Ryan *et al.*<sup>2</sup> and Bartolini *et al.*<sup>10</sup>. Moreover, a careful evaluation of specific heavy mineral types in our Ridge core sample separations reveals other significant differences: a somewhat higher proportion of brown hornblende, serrated or saw-tooth pyroxenes (Fig. 2a), angular apatite (Fig. 2c); the presence of a few glaucophane grains; and a markedly higher proportion of both garnet and opaque minerals in the DSDP Site 130 samples. Examples of the more typical rounded pyroxene and apatite grains in the Nile Cone are shown for contrast in Fig. 2b and d.

The compositional differences between sands in the lower Nile Cone–Herodotus Basin plain sector and those on the southern part of the Ridge also are recorded in the light mineral fractions. There is a relatively higher proportion of fresh to slightly altered and angular feldspar grains on the Ridge (Fig. 2e) than in DSDP Site 131 and other Nile Cone core samples where subangular to rounded altered grains prevail (Fig. 2f). In DSDP Site 131 and other Nile Cone core samples, there is a strong wavy extinction: normal–weakly wavy extinction ratio of about 2:1. Two samples of DSDP Site 130 contain quartz with primarily normal or weakly wavy extinction, and three with strongly wavy extinction; most quartz in Ridge core P6510–17 also displays strong wavy extinction.

More distinct regional differences are recorded by the nature and frequency of quartz inclusions: samples from DSDP Site

130 and P-6510–17 tend to show fewer solid (rutile needles, zircon, apatite) and fluid–gaseous inclusions than in DSDP Site 131 and Nile Cone and outer Shelf samples (Fig. 3a, b) and in comparable Nile Delta sands as earlier detailed by Kholief<sup>18</sup>. Some quartz grains from Ridge core P6510–17 (sands sampled at 149 and 452 cm from top of core) and DSDP Site 130 (sample 4–2) are characterised by angular overgrowths over euhedral and subhedral crystals (Fig. 3c), unlike some quartz from the

**Fig. 2** Photomicrographs showing details of some heavy and light minerals from the southern Mediterranean Ridge (a,c,e) and Nile Cone (b,d,f) core samples. a, Saw-tooth amphibole (Pillsbury 6510–17, 452 cm) scale bar, 10 μm; b, subrounded amphibole (DSDP Site 131–6, 129–131 cm) scale bar, 100 μm; c, angular apatite (DSDP Sites 130–5–3, 125–126 cm) scale bar, 25 μm; d, rounded apatite (DSDP Site 131A–4–2, 117–119 cm) scale bar, 15 μm; e, fresh, angular plagioclase feldspar (Pillsbury 6510–17, 452 cm) scale bar, 15 μm; f, subrounded, worn-edged plagioclase feldspar (Vema 10–57, 690–691 cm) scale bar, 15 μm.

\* Key to sample stations: 13 refers to DSDP 1970 leg 13 Sites 130, 131 and 131A, with drill core and section numbers as in ref. 2; P, University of Miami cruise Pillsbury 6508 and 6510 piston and gravity cores<sup>20</sup>; V, Lamont-Doherty Geological Observatory cruise Vema 10 piston cores<sup>12</sup>; CHN, Woods Hole Oceanographic Institution cruise Chain 119 grab samples<sup>19</sup>.

† Depth in centimetres from piston and gravity core tops or DSDP core section top.

‡ Zircon + tourmaline + rutile.

§ Includes altered as well as unidentified grains.

<sup>a</sup> Angular apatite; <sup>b</sup> brown hornblende present to common; <sup>c</sup> angular and saw-tooth pyroxenes; and <sup>d</sup> presence of few glaucophane grains.

Nile Cone and Egyptian Shelf which display partial rounded overgrowths on rounded grains (Fig. 3d). Some angular quartz grains of the Ridge show no evidence of wear. Also significant are angular and euhedral quartz and feldspar grains (found only in DSDP Site 130, samples 4-2 and 5-3) that display a type of radiating crack pattern with fissures that extend from the centre towards the edge of the grain; the intensity of fissuring decreases outward (Fig. 3e). This pattern is in marked contrast with quartz, usually rounded, in the Delta and on the Shelf and Nile Cone, which more commonly displays one or two generations of cracks (Fig. 3f).

## Evidence for mixed Nile-proximal provenance

The mineralogical composition of terrigenous sand-sized material in surficial Egyptian Shelf and Quaternary Nile Cone samples, including DSDP Site 131, are genetically related to a Nile apport. The large station-to-station differences in the relative percentage of heavy minerals in the surficial Egyptian Shelf samples primarily reflect size sorting and density concentration (lag) effects due to sea floor processes that have reworked both modern and relict sediments<sup>19</sup>. During the Pleistocene, Nile-

derived sandy fluvial, deltaic and eolian deposits were emplaced downslope by gravity-induced resedimentation processes<sup>2,10,12,20</sup>. The observed fluctuations in relative percentages of heavy minerals between samples within any core and between piston core localities on the different parts of the Nile Cone proper more closely record differences of processes than changes in provenance. This is demonstrated, for example, by the progressive diminution downslope, in the same textural grade, of denser opaque minerals. Both heavy and light mineral suites in Nile Cone Quaternary short piston core and DSDP Site 131 samples are essentially comparable with those described in the main Nile by Shukri<sup>15,16</sup>, and in the sediments of the Delta and related Nile-derived older sections<sup>14,17,21</sup>, which show a contribution (including relatively high percentages of pyroxenes) from the Blue Nile, Atbara and other tributaries draining the Abyssinian volcanic source terrains.

Although composition of the probable lower to middle Pleistocene sands at DSDP Site 130 and Pleistocene sands in Pillsbury core 6510-17 is broadly similar to the Nile-derived sediment on the Nile Cone, our investigation emphasises some significant mineralogical differences on the southern part of the Ridge. We believe that the distinct suite of mineral species in the Ridge samples indicates input from a more proximal source terrain in addition to the Nile-derived sands. The much higher proportion of amphiboles in southern Ridge cores is not, as previously suggested, due only to a finer grain size in this more distal sector; examination of comparable textural grades in Nile Cone DSDP Site 131 and Vema 10-53, 55 and 57 core samples all show substantially lower proportions of amphiboles than in DSDP Site 130 and P6510-17 core samples (Fig. 1). Furthermore, the greater proportion of angular grains of both heavy and light components (apatite, serrated pyroxenes, quartz, feldspar), an increased percentage of unaltered feldspar grains, apatite and brown hornblende, the presence of glaucophane grains, angular quartz overgrowth on euhedral and subhedral quartz grains, a radiating crack pattern within some euhedral quartz and feldspar grains, and a generally lower proportion of solid inclusions in quartz grains identify a mineralogical assemblage distinct from that in the modern to pre-Quaternary main Nile, Nile Delta and Nile coastal deposits.

The angular, serrated and non-altered state of various mineral species in the Ridge samples records minimum weathering-abrasion effects; this is in contrast with the reworked, subangular to rounded and often altered grains on the Egyptian Shelf and Nile Delta that invariably show considerable effect of one or multi-cycle fluvial or eolian (or both) transport. The immature mineral fraction in DSDP Site 130 and P6510-17 sands records the introduction of material from more proximal plutonic igneous and possibly also metamorphic sources rather than from distal African terrains. The compositional mix of reworked Nile-derived material and 'fresh' components would imply the addition of new sediment at some point between the Nile Delta-Egyptian Shelf sector and the Ridge core localities. As most of the sands examined in cores DSDP Site 130 and P6510-17 were emplaced by turbidity currents and associated gravity induced mass-flow processes, we are required to consider some modification of the direct downslope SE to NW dispersal path that has prevailed in this sector during the late Quaternary<sup>12,20</sup>.

## Two-phase dispersal pattern

Where did the fresh sedimentary material enter the transport system? An extensive seismic survey of the Nile Cone by Ross and Uchupi<sup>3</sup> does not reveal basement series at or near the surface between the Nile Delta and the Ridge, and we exclude a southerly position for the introduction of fresh minerals. Transport from a northern Hellenic Arc-Crete source is precluded on the basis of the heavy mineral composition which is significantly different in that sector, a view also adopted by Bartolini *et al.*<sup>10</sup>. Cyprus and the Eratosthenes Seamount, located approximately 300 km NE and E of the sample sites, while not excluded, seem to be unlikely source areas. We can do

**Fig. 3** Photomicrographs showing details of quartz from Nile Cone and Mediterranean Ridge core samples. *a*, Quartz with inclusions of partially altered zircon (*z*), segmented rutile needles (*r*) and orientated minute gas (*g*) bubbles (outer Egyptian Shelf, Pillsbury 6510-10, 90 cm); rutile segments are of variable length and arranged in a regular pattern; scale bar, 55  $\mu$ m. *b*, Quartz with non-orientated inclusions of apatite (*a*) and rutile (*r*) needles (outer Egyptian Shelf, Pillsbury 6510-10, 90 cm) scale bar, 20  $\mu$ m. *c*, Angular secondary overgrowth (*O*) on subhedral quartz, with orientated cracks and green solid inclusions (southern Mediterranean Ridge, Pillsbury 6510-17, 452 cm) scale bar, 10  $\mu$ m. *d*, Rounded secondary overgrowth (*O*) partially surrounding a subrounded quartz grain, which shows a system of orientated cracks with secondary inclusions (outer Egyptian Shelf, Pillsbury 6510-10, 90 cm) scale bar, 55  $\mu$ m. *e*, Subhedral quartz with radiating crack pattern displaying fissures that extend outwards from the centre of the grain (southern Mediterranean Ridge, DSDP Site 130-5-2, 90-91 cm) scale bar, 50  $\mu$ m. *f*, Round quartz grain displaying two generations of cracks lined with secondary inclusions, and an apatite (*a*) solid inclusion (outer Egyptian Shelf, Pillsbury 6510-10, 90 cm) scale bar, 55  $\mu$ m.

little more, at this point, than invoke a two-phase dispersal pattern: transport downslope of recycled African sand on the Nile Cone surface in a direction away from the Nile Delta to an area north of the present Herodotus Basin plain during a first stage of Nile Cone progradation<sup>2</sup>, and then a remobilisation and subsequent short-distance transport of this Nile-derived material to which a distinct igneous and metamorphic fraction has been added in the Ridge area. The topographically complex configuration of the Ridge is of geologically recent origin, and it is possible that some resedimentation occurred during the Pleistocene in the area where transport would not be possible on the present Ridge surface.

Immature mineral assemblages in Pleistocene sands of the short P-6510-17 core, about 90 km NE of the much older Pleistocene DSDP Site 130 locality, strengthens the hypothesis of yet undefined igneous-metamorphic sources in the south-central Ridge area. The possibility of a surface or near-surface exposure of sub-sedimentary basement on the Ridge should not be readily dismissed although no specific evidence for this has been provided by gravity measurements or seismic profiles. Our findings, not inconsistent with compressive thrust-belt<sup>8</sup> and décollement<sup>22</sup> reconstructions, suggest that possibility of some movement of basement, perhaps as part of an allochthonous

slice. The petrographic evidence indicating local input should be considered in developing an interpretive scheme for the Mediterranean Ridge.

We thank the NSF (DSDP Site 130 and 131 cores), University of Miami School of Marine and Atmospheric Science (P-6510 cores), Lamont-Doherty Geological Observatory of Columbia University (Vema 10 cores) and Woods Hole Oceanographic Institution (Chain 119 grab samples) for generously providing samples. Dr Andrés Maldonado assisted in sampling and Drs W. G. Melson and D. A. Ross reviewed the manuscript. This study, part of the Mediterranean Basin (MEDIBA) Project, was funded by a Smithsonian Research Award (FY-79 grant 89191028).

# Characterisation of deletions which affect the expression of fetal globin genes in man

Edward F. Fritsch, Richard M. Lawn & Tom Maniatis

Division of Biology, California Institute of Technology, Pasadena, California 91125

*Deletions in the DNA of individuals with hereditary persistence of fetal haemoglobin (HPFH) and  $\delta\beta$ -thalassaemia have been mapped as a means of identifying regulatory sequences involved in the switch from fetal to adult globin gene expression. The end points of these deletions have been precisely located with respect to restriction endonuclease cleavage sites within and surrounding the  $\gamma$ -,  $\delta$ - and  $\beta$ -globin genes in normal human DNA and the deletion maps were used to obtain definitive evidence for the physical linkage of the fetal and adult  $\beta$ -like globin genes in the order 5' $\gamma$ - $\delta$ - $\beta$ 3'. Correlation of haematological data and the location of deletions in two cases of HPFH and one case of  $\delta\beta$ -thalassaemia suggest that a region of DNA located near the 5'-end of the  $\delta$ -globin gene may be involved in the suppression in cis of  $\gamma$ -globin gene expression in adults. The interpretation of a second case of  $\delta\beta$ -thalassaemia is complicated by the fact that the deletion removes the  $\gamma$ -gene in addition to the region near the 5'-end of the  $\delta$ -globin gene.*

HUMAN globin genes provide a unique system for studying the nature of mutations which alter the normal programme of differential gene expression during mammalian development. For example, in normal individuals the fetal  $\beta$ -like globin genes, designated  $\gamma$  and  $\delta$ , are turned down at 32–34 weeks of gestation, while the adult  $\beta$ -like genes, designated  $\delta$  and  $\beta$ , are turned up. Certain genetic disorders have been described in which this control 'switch' is altered (see refs 1, 2 for reviews); in that designated hereditary persistence of fetal haemoglobin (HPFH)<sup>1–12</sup>, often neither the  $\delta$ - nor the  $\beta$ -globin chains are synthesised in adult erythroid cells, but one or both of the

$\gamma$ -globin genes continue to be expressed, compensating for the  $\beta$ -globin deficiency. In  $\delta\beta$ -thalassaemia, no  $\delta$ - or  $\beta$ -globin chain synthesis is detected in adults, but in contrast to HPFH, compensation by continued fetal globin synthesis is incomplete. The resulting imbalance of  $\alpha$ - and non- $\alpha$ -globin polypeptide synthesis in homozygous  $\delta\beta$ -thalassaemia leads to anaemia and red cell abnormalities characteristic of thalassaemia syndromes<sup>1</sup>. Differences in the pattern of globin gene expression in individuals with HPFH and  $\delta\beta$ -thalassaemia led to the proposal that sequences necessary for the repression of  $\gamma$ -globin gene expression in the adult might be deleted in HPFH DNA<sup>7</sup>. In fact, when DNAs from individuals homozygous for HPFH or  $\delta\beta$ -thalassaemia were examined by solution hybridisation experiments, extensive deletions of  $\beta$ -globin gene sequences were observed<sup>3–6</sup>. This result was confirmed<sup>9,10</sup> using the blot hybridisation technique of Southern<sup>13</sup> to map single copy genes<sup>14,15</sup>. Mapping deletions in HPFH and  $\delta\beta$ -thalassaemia may provide insights into the mechanism of the switch from fetal to adult globin gene expression.

Advances in physical mapping and gene cloning procedures have made it possible to determine the linkage arrangement of human fetal and adult globin genes and have provided hybridisation probes for examining DNA which lies outside gene sequences. Previous genetic evidence<sup>1,2</sup> and structural analysis of the fusion proteins Lepore<sup>16</sup> and Kenya<sup>17</sup> suggested that the fetal and adult  $\beta$ -like globin genes are linked. Physical linkage of the  $\delta$ - and  $\beta$ -globin genes<sup>18,19</sup> and of the  $\gamma$ - and  $\delta$ -globin genes<sup>20</sup> was demonstrated using blot hybridisation<sup>13</sup> and gene cloning<sup>21</sup> procedures. Physical linkage between  $\delta$ - $\beta$  and  $\gamma$ - $\delta$  gene loci has not been demonstrated.

In this report we use cloned complementary DNA and genomic DNA fragments as probes in blot hybridisation experiments to map the end points of deletions in DNA from individuals homozygous for HPFH or  $\delta\beta$ -thalassaemia. In addition, we unambiguously demonstrate direct physical linkage between the fetal and adult globin genes.

## Deletion mapping

Deletions in two cases each of homozygous hereditary persistence of fetal haemoglobin (HPFH-1 and 2)<sup>3,5,11,12</sup> and of homozygous  $\delta\beta$ -thalassaemia ( $\delta\beta$ -1 and 2)<sup>9,10,22</sup> were mapped relative to restriction endonuclease cleavage sites within and surrounding the  $\gamma$ -,  $\delta$ - and  $\beta$ -globin genes in normal human DNA. The map of these cleavage sites in normal DNA shown in Fig. 1a was derived by analysis of cloned globin genes<sup>19</sup> and by blot hybridisation experiments described here and elsewhere<sup>18,20,24</sup>. To scan the entire  $\beta$ -like gene locus systematically for the location of deletions, blots of each type of mutant DNA were first hybridised individually with *in vitro* labelled  $\beta$ - or  $\gamma$ -globin cDNA plasmids<sup>25</sup> or with a cloned DNA fragment from a region between the adult and fetal globin genes. Precise localisation of the end points of the deletions was then accomplished by additional enzyme digestions as described in detail below.

## HPFH-1 DNA

HPFH-1 DNA was obtained from an individual homozygous for a type of HPFH in which both the  $\gamma$  and  $\gamma$  polypeptides are produced in adults<sup>3</sup>. Initially, normal and HPFH-1 DNA were compared by blot hybridisation procedures using the  $\beta$ -globin cDNA plasmid as probe (Fig. 2a). As expected from the restriction map of Fig. 1a, digestion of normal DNA with *EcoRI* produces four fragments (5.2, 3.6, 2.3 and 1.75 kilobases) which hybridise the  $\beta$ -globin cDNA probe (Fig. 2a). Similarly, digestion with *TaqI* produces two hybridising fragments (8.5 and 3.0 kilobases) while digestion with *XbaI* produces a single hybridising fragment (10.8 kilobases). In contrast, no hybridising fragments are observed following digestion of HPFH-1 DNA, indicating that, in agreement with liquid hybridisation<sup>3</sup> and blot hybridisation<sup>10</sup> experiments, HPFH-1 DNA has little or no  $\beta$ - or  $\delta$ -globin gene sequences.

Fragments characteristic of normal DNA were observed when HPFH-1 DNA was digested with *EcoRI*, *BglII* or *SacI* and hybridised to the  $\gamma$ -globin probe (Fig. 2b). These results indicate that the left end point of the deletion in HPFH-1 DNA is located to the left of the  $\delta$ -globin gene as shown in Fig. 1a. We therefore hybridised blots of HPFH-1 DNA with a cloned 0.5-kilobase fragment which lies 4 kilobases to the left of the  $\delta$ -globin gene<sup>19</sup> ('RIH'; see Fig. 1a) to determine whether the RIH sequence is present in HPFH-1 DNA and to map the surrounding restriction enzyme sites. As shown in Fig. 3a, a 7.2-kilobase fragment is observed in both normal and HPFH-1 DNA digested with *EcoRI*, indicating that the RIH sequence is present and that the end point of the HPFH-1 deletion is located to the right of RIH.

To map this end point further, additional enzyme digests were carried out. Digestion of normal DNA with *PstI*, *XbaI* or *TaqI* yields single fragments of 4.8, 1.2 and 2.0 kilobases, respectively, which hybridise to the RIH probe (Fig. 3b). Double digests with *EcoRI* were carried out to map these sites in normal DNA with respect to RIH. Fragments of 3.2 kilobases (*PstI/EcoRI*), 0.5 kilobases (*XbaI/EcoRI*), and 1.6 kilobases (*TaqI/EcoRI*) were observed. These results identify *PstI*, *XbaI* and *TaqI* cleavage sites 3.2, 0.5 and 1.6 kilobases, respectively, to the left of the *EcoRI* site at the right end of RIH. By subtraction from the size of the single digest products, *PstI*, *XbaI* and *TaqI* sites lie 1.6, 0.7 and 0.4 kilobases to the right of this *EcoRI* site (see Fig. 1a).

Similar single and double enzyme digests were carried out with HPFH-1 DNA to determine which of these sites is altered (Fig. 3b). The sizes of the RIH hybridising fragments in the double enzyme digests are identical to those observed with normal DNA, indicating that the *PstI*, *XbaI* and *TaqI* sites to the left of RIH are not altered in HPFH-1 DNA. However, the sizes of all the hybridising fragments produced in single enzyme digests are altered, indicating that sites to the right of RIH are removed by the deletion (Fig. 3b). These data place the end

**Fig. 1** A map of restriction endonuclease cleavage sites within and surrounding the human  $\gamma$ -,  $\delta$ - and  $\beta$ -globin genes. *a*, The arrangement of fetal and adult  $\beta$ -like globin genes within a 43-kilobase segment of human DNA. Physical linkage of the adult  $\delta$ - and  $\beta$ -globin genes<sup>18,19</sup> and the fetal  $\gamma$ - and  $\gamma$ -globin genes<sup>20</sup> has been previously described. The physical linkage of the fetal and adult globin genes is described in the text. The direction of transcription of the four linked genes is left to right ( $5' \rightarrow 3'$ ). The solid boxes represent the locations of mRNA coding regions. The open boxes represent the large non-coding intervening sequence in each gene<sup>18-20,23,24</sup>. This intervening sequence is located between codons 104 and 105 in the  $\delta$ ,  $\beta$  (ref. 19) and  $\gamma$  (ref. 23) genes. Sizes of the  $\gamma$ -,  $\gamma$ -,  $\delta$ - and  $\beta$ -globin intervening sequences are approximately 850, 850, 950 and 900 base pairs, respectively. A smaller intervening sequence identified in the  $\beta$ - and  $\gamma$ -genes and presumably present in the  $\gamma$ - and  $\delta$ -genes is not shown. The brackets below the gene map indicate the positions of the *XbaI*, *RIH* and *PstI* fragments. These fragments are used as hybridisation probes in some experiments and are described in detail in the appropriate figure legends. For each of the restriction endonucleases indicated on the left, the relative locations of cleavage sites are marked by a vertical line. The sizes for the restriction enzyme fragments are given in kilobases. Question marks indicate that the presence of additional cleavage sites has not been determined. The locations of cleavage sites within the region delineated by the upward-pointing arrows were determined from an analysis of the clone HBG1 which contains the linked  $\delta$ - and  $\beta$ -globin genes (ref. 19 and our unpublished results). Some cleavage sites within the region delineated by the downward-pointing arrows were determined by an analysis of the clone HYG1 which contains the  $\gamma$ - and  $\gamma$ -globin genes (unpublished results). Additional cleavage sites within and surrounding the  $\gamma$ -,  $\delta$ - and  $\beta$ -globin genes were mapped by blot hybridisation experiments (refs 18, 20, and this paper). *b*, The regions of the  $\beta$ -like globin gene locus deleted in HPFH and  $\delta\beta$  DNAs are indicated by solid boxes. The precise locations of the end points of the deletions are within the regions specified by the hatched boxes. The locations of the rightward ends of the deletions are not known.

point of the HPFH-1 deletion within the 400-base pair region between the *EcoRI* site bounding the RI H fragment and the *TaqI* site to the right. The deletion therefore extends from approximately 4 kilobases to the left of  $\delta$  to at least 4 kilobases beyond the 3' end of the  $\beta$ -globin gene, which is the rightward limit of our restriction map. Thus, the deletion in HPFH-1 DNA removes at least 16 kilobases of DNA (Fig. 1b).

## HPFH-2 DNA

DNA from a second case of homozygous HPFH was also examined<sup>10-12</sup>. This DNA was obtained from an individual apparently unrelated to the HPFH-1 case. As with HPFH-1, HPFH-2 lacks the  $\delta$ - and  $\beta$ -globin genes and contains no detectable alteration within or closely surrounding the  $\gamma$ -globin genes (data not shown). When HPFH-2 DNA was examined in an experiment identical to that of Fig. 3b, an identical result was obtained (data not shown). Therefore, the deletion in HPFH-2 DNA is indistinguishable from that in HPFH-1 DNA.

## $\delta\beta$ -1 DNA

Hybridisation of  $\delta\beta$ -1 DNA with the  $\gamma$ -globin probe revealed fragments characteristic of normal DNA (Fig. 2b). However, with the  $\beta$ -globin probe (Fig. 2a) a single hybridising fragment was observed in  $\delta\beta$ -1 DNA digested with *EcoRI* (3.0 kilobases) (see also ref. 9), *TaqI* (2.3 kilobases) and *XbaI* (2.5 kilobases). All these sizes differ from those found in normal DNA. This result indicates that a portion of either the  $\beta$ - or  $\delta$ -globin gene is

**Fig. 2** Hybridisation of normal, HPFH-1 and  $\delta\beta$ -1 DNAs with cloned  $\beta$ - and  $\gamma$ -globin cDNA probes. Human DNA was isolated from transformed lymphoid cells<sup>3,9</sup> using the procedure of Blin and Stafford<sup>26</sup>. DNA samples were digested separately with *EcoRI*, *TaqI* or *XbaI*, electrophoresed in a horizontal 0.8% agarose slab gel and transferred to nitrocellulose filter paper<sup>13</sup>. The *HhaI* fragments containing  $\beta$ - or  $\gamma$ -globin cDNA sequences were isolated from the plasmids pJW102 or pJW151 (ref. 25), respectively, labelled with <sup>32</sup>P by nick translation<sup>27</sup> and hybridised to the filter-bound DNA<sup>13,15</sup>. (The recombinant DNA containment level of P3<sup>+</sup> EK2 was used as outlined in the National Institutes of Health Recombinant DNA Research Guidelines.) Following hybridisation the filters were washed sequentially in 1×, 1/2× and 1/4× washing buffer at 68 °C (1× buffer is 50 mM NaCl, 10 mM Tris-HCl, pH 7.5, 1 mM EDTA, 0.1% SDS) and exposed to X-ray film using two DuPont Cronex lighting plus intensifier screens. Bacteriophage  $\lambda$  DNA digested with *HindIII* (ref. 19) and pBR322 DNA digested with *HinfI* (ref. 28) were included in the gel as size standards. The positions of some of the markers are indicated to the left of the autoradiogram (in kilobase pairs). *a*, Digests of  $\delta\beta$ -1, HPFH-1 and normal (N) DNA hybridised with the  $\beta$ -globin probe. The position of the weakly hybridising 1.75-kilobase 3'- $\delta$  *EcoRI* fragment is indicated by the dot. *b*, Digests of the same DNAs hybridised with the  $\gamma$ -globin probe. Two additional *EcoRI* fragments (1.6 and 0.6 kilobases)<sup>20</sup> are not detected by the  $\gamma$ -globin cDNA plasmid used here, which lacks a portion of the 3'-mRNA sequence.

present in  $\delta\beta$ -1 DNA. Hybridisation of *BamHI*-digested  $\delta\beta$ -1 DNA with the RI H probe revealed a fragment identical to that found in normal DNA (data not shown). This result suggests that  $\delta\beta$ -1 DNA might contain 5'- $\delta$ -gene sequences, as the *BamHI* site nearest to the RI H fragment is located within the  $\delta$ -gene. The restriction enzyme *PvuII* was used to demonstrate the presence of 5'- $\delta$ -sequences of  $\delta\beta$ -1 DNA. A *PvuII* site is present in the 5'-end of the  $\delta$ -globin gene and no other *PvuII* sites are found in either the  $\beta$ - or  $\delta$ -globin genes<sup>18</sup>. To detect  $\delta$ -globin gene sequences we used a cloned *PstI* fragment ('*Pst*  $\delta$ '; see Fig. 1a) which contains the  $\delta$ -globin gene and surrounding sequences.

Digestion of  $\delta\beta$ -1 DNA with *PstI* produces a single fragment of 10.5 kilobases which hybridises to the *Pst*  $\delta$  probe. Fragments of 7.3 and 0.9 kilobases are produced in a *PstI*/*PvuII* double digest (Fig. 4a). The presence of a fragment which is cut by *PvuII* to produce two fragments which hybridise the  $\delta$ -globin probe indicates that a portion of the  $\delta$ -globin gene is retained in  $\delta\beta$ -1 DNA. A similar conclusion was obtained from *EcoRI* and *PvuII* digests (data not shown).

A *BamHI* site is located to the right of the *PvuII* site in the  $\delta$ -globin gene. To determine whether this *BamHI* site is present in  $\delta\beta$ -1 DNA, double digests with *BamHI* were carried out. A *BamHI*/*PstI* digest of normal DNA produces fragments of 0.95 and 1.35 kilobases which hybridise the *Pst*  $\delta$  probe (Fig. 4b; a weakly hybridising  $\beta$ -gene fragment is also seen). The 0.95-kilobase fragment corresponds to the *PstI*/*BamHI* fragment to the left of the intragenic *BamHI* site, whereas the 1.35-kilobase fragment corresponds to the *BamHI*/*PstI* fragment to the right of this site. A *BamHI*/*PstI* digest of  $\delta\beta$ -1 DNA produces a 0.95 and a 3.3-kilobase fragment but no 1.35-kilobase fragment. Similarly, a *BamHI*/*EcoRI* digest of normal DNA produces fragments of 1.3, 1.0 and 1.75 kilobases (plus a  $\beta$ -gene fragment). The 1.3-kilobase fragment corresponds to the *EcoRI*/*BamHI* fragment to the left of the intragenic *BamHI* site; the 1.0-kilobase fragment to the *BamHI*/*EcoRI* fragment containing the  $\delta$ -globin intervening sequence; and the 1.75-kilobase fragment to the *EcoRI* fragment containing the 3'-portion of the  $\delta$ -globin gene. A *BamHI*/*EcoRI* digest of  $\delta\beta$ -1 DNA produces a 1.3-kilobase 5'- $\delta$ -gene fragment and a 1.9-kilobase fragment but not the 1.0- or 1.75-kilobase fragments of normal DNA. Together these results indicate that the restriction enzyme sites leftward from the intragenic *BamHI* site are present and that the *EcoRI* and *PstI* sites to the right of the *BamHI* site are missing in  $\delta\beta$ -1 DNA. This conclusion was confirmed by comparing *EcoRI*/*PvuII* or *PstI*/*PvuII* digests of normal and  $\delta\beta$ -1 DNAs (data not shown).

To further delineate the end point of the deletion, we compared the *HpaI* digestion patterns of normal and  $\delta\beta$ -1 DNA, as an *HpaI* site is located within the intervening sequence of the  $\delta$ -globin gene approximately 150 base pairs to the left of the *EcoRI* site (unpublished results). Digestion of normal DNA with *HpaI* produces fragments of 1.9 and 1.4 kilobases which hybridise with the  $\delta$ -globin probe (Fig. 4c; a large  $\beta$ -gene fragment is also observed). The 1.9-kilobase fragment contains the  $\delta$ -globin gene and the portion of the intervening sequence to the left of the *HpaI* site, and the 1.4-kilobase fragment contains sequences to the right of the *HpaI* site. Digestion of  $\delta\beta$ -1 DNA yields only one hybridising fragment of 2.1 kilobases, indicating that at least two of the three *HpaI* sites which delineate the 1.9- and 1.4-kilobase fragments in normal DNA are missing. Additional experiments using the RI H probe indicate that the *HpaI* site to the left of the  $\delta$ -globin gene in normal DNA is present in  $\delta\beta$ -1 DNA (data not shown). Therefore, the *HpaI* site near the right end of the intervening sequence is absent in  $\delta\beta$ -1 DNA.

In double digests with *BamHI* and either *PstI* or *EcoRI*, sequences to the right of the *BamHI* site hybridised to the *Pst*  $\delta$  probe. To form a stable hybrid in the conditions used, more than the 12 base pairs of coding sequence between the *BamHI* site and the beginning of the intervening sequence are required. Hence, at least some of the  $\delta$ -globin intervening sequence must be present in  $\delta\beta$ -1 DNA. Therefore, the deletion in  $\delta\beta$ -1 DNA

**Fig. 3** Hybridisation of normal and HPFH-1 DNA with the RI H fragment. Normal and HPFH-1 DNAs were hybridised as in Fig. 2 with *in vitro* labelled RI H DNA. The RI H fragment in H $\beta$ G1 DNA is located approximately 4 kilobases to the left of the  $\delta$ -globin gene (Fig. 1a) and is bounded on the right end by an *Eco*RI site present in genomic DNA and on the left end by an artificial *Eco*RI site created during the construction of the human DNA library<sup>19</sup>. The RI H fragment was isolated from H $\beta$ G1, subcloned into the *Eco*RI site of the plasmid pMB9 (ref. 29) and grown in *Escherichia coli*  $\chi$ 1776 (ref. 30). The RI H fragment was isolated from purified plasmid DNA of the subclone following *Eco*RI digestion. a, *Eco*RI digest; b, single and double enzyme digests using *Taq*I, *Xba*I and *Pst*I with *Eco*RI.

begins within the large intervening sequence of the  $\delta$ -globin gene and extends to at least 4 kilobases to the right of the  $\beta$ -globin gene (Fig. 1b).

### $\delta\beta$ -2 DNA

When  $\delta\beta$ -2 DNA<sup>10</sup> was digested with various restriction endonucleases, blotted and hybridised with the  $\beta$ -globin probe, no hybridisation was observed (ref. 10 and our unpublished results). Moreover, we detect no hybridisation with the RI H probe. The deletion in  $\delta\beta$ -2 DNA therefore extends through the  $\delta$ - and  $\beta$ -globin genes and beyond the RI H sequence. We next determined whether the deletion also covers restriction enzyme sites near the  $\gamma$ -globin genes. In *Bgl*II digests of normal DNA a 13-kilobase fragment containing both  $\gamma$ -globin genes was detected (Fig. 5a). However, in  $\delta\beta$ -2 DNA a 7-kilobase fragment was observed, indicating that one of the two *Bgl*II sites surrounding the  $\gamma$ -globin genes is deleted in  $\delta\beta$ -2 DNA. Digestion of normal DNA with *Eco*RI produces fragments of 7.2 and 2.7 kilobases which contain the 5'-portions of the  $\gamma$  and  $\delta$ -genes, respectively<sup>20</sup>. (Two fragments of 1.7 and 0.8 kilobases containing the 3' portions of these genes<sup>20</sup> are not efficiently detected with the pJW151  $\gamma$  cDNA probe.) Only the 7.2-kilobase 5'  $\gamma$  fragment was detected in  $\delta\beta$ -2 DNA. Thus, part or all of the  $\delta$ -gene is deleted in  $\delta\beta$ -2 DNA and sequences to the left of and including the intragenic *Eco*RI site in the  $\gamma$ -gene are present. This conclusion is consistent with the *Bam*HI hybridisation pattern. *Bam*HI digestion of normal DNA produces fragments of 15.5, 5.1 and 2.6 kilobases which hybridise to the  $\gamma$ -globin probe (Fig. 5b). These fragments contain, respectively, 3'  $\delta$ , 3'  $\gamma$  plus 5'  $\delta$ , and 5'  $\gamma$  sequences. Only the 5'  $\gamma$  fragment is observed in *Bam*HI digests of  $\delta\beta$ -2 DNA. The end point of the deletion within the

$\gamma$ -globin gene locus was more precisely mapped using the enzyme *Sac*I.

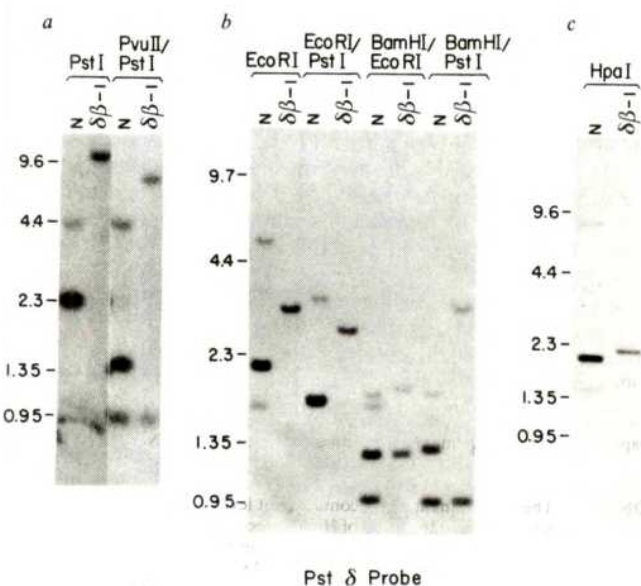

*Sac*I digestion of normal DNA produces fragments of 3.8 and 2.7 kilobases which hybridise the  $\gamma$ -globin probe (Fig. 5b). These fragments contain the  $\delta$ - and  $\gamma$ -gene sequences, respectively. *Sac*I digestion of  $\delta\beta$ -2 DNA produces only the 2.7-kilobase  $\gamma$  fragment, indicating that the *Sac*I site to the right of the  $\gamma$ -intragenic *Eco*RI site is present in  $\delta\beta$ -2 DNA. No additional fragments were observed, again implying that part or all of the  $\delta$ -gene is deleted.

To determine whether the *Eco*RI site to the right of the  $\gamma$ -gene is present in  $\delta\beta$ -2 DNA, a cloned genomic DNA fragment containing 3'  $\gamma$  sequences was used as a probe (*Xba*  $\gamma$ ; Fig. 1). Figure 5c shows the *Eco*RI lanes from the filter of Fig. 5a reprobed with the *Xba*  $\gamma$  fragment. With the *Xba*  $\gamma$  probe the 1.7-kilobase 3'  $\gamma$  *Eco*RI fragment of normal DNA is detected (compare Fig. 5a and c). This fragment is missing in  $\delta\beta$ -2 DNA, indicating that the deletion removes the *Eco*RI site to the right of the  $\gamma$ -gene. Thus, the deletion in  $\delta\beta$ -2 DNA begins in the region between the *Sac*I site within the  $\gamma$ -gene<sup>32</sup> and the *Eco*RI site to the right of the gene and extends through the  $\delta$ -gene. The same (or possibly a second) deletion extends through the RI H,  $\delta$ - and  $\beta$ -globin sequence (Fig. 1b).

### Physical linkage of $\gamma$ -, $\delta$ - and $\beta$ -globin genes

Linkage between the fetal and adult globin genes was suggested by structural analysis of Hb Kenya<sup>17</sup>, a fusion protein consisting of  $\delta$ -globin N-terminal and  $\beta$ -globin C-terminal sequences. However, direct physical linkage has not been demonstrated. We have used cloned genomic DNA hybridisation probes and the deletion map of HPFH-1 DNA (Fig. 1b) to demonstrate unambiguously physical linkage between the  $\delta$ - and  $\beta$ -globin genes.

Initially, we identified large restriction enzyme fragments in normal DNA which hybridise the  $\gamma$ -globin and RI H probes. As shown in Fig. 6a the RI H probe hybridises with a 15.5-kilobase *Bam*HI fragment and a 14.0-kilobase *Hpa*I fragment in normal

**Fig. 4** Hybridisation of normal and  $\delta\beta$ -1 DNAs with the  $\delta$ -globin *Pst*I fragment. Normal and  $\delta\beta$ -1 DNAs were hybridised as described in the legend to Fig. 2 with *in vitro* labelled *Pst*  $\delta$  DNA. The *Pst*  $\delta$  fragment of H $\beta$ G1 DNA contains the  $\delta$ -globin gene and some surrounding sequences (Fig. 1a). The *Pst*  $\delta$  fragment was isolated from H $\beta$ G1, subcloned into the *Pst*I site of the plasmid pBR322 (ref. 31) and grown in *E. coli*  $\chi$ 1776 (ref. 30). The *Pst*  $\delta$  fragment was isolated from the purified plasmid DNA of the subclone following *Pst*I digestion. a, *Pst*I/*Pvu*II double digest; b, double digests using *Eco*RI, *Pst*I and *Bam*HI; c, *Hpa*I digest.

DNA. Fragments of these sizes are also detected using the pJW151  $\gamma$ -gene probe (Fig. 6b) or a probe specific for the 3'-end of the  $\gamma$ -genes (Fig. 6c). The 15.5-kilobase fragment corresponds to a 15-kilobase fragment which was previously shown to contain 3'- $\gamma$ -sequences<sup>20</sup>. Our mapping experiments (unpublished) indicate that the 14.0-kilobase *Hpa*I fragment also contains 3'- $\gamma$ -sequences. These results indicate that RI H and 3'- $\gamma$ -sequences are present on fragments of identical size in *Bam*HI or *Hpa*I digests. Thus, the 3' end of the  $\gamma$ -gene seems to be linked to the RI H fragment. Definitive evidence for this linkage relationship was obtained by comparing the sizes of the *Bam*HI and *Hpa*I fragments in normal and HPFH-1 DNA using RI H and  $\gamma$ -globin probes. If the linkage arrangement proposed above is correct, the deletion in HPFH-1 should alter the size of the *Bam*HI and *Hpa*I fragments detected by both the RI H and  $\gamma$ -probes. As predicted, the 15.5-kilobase *Bam*HI and 14.0-kilobase *Hpa*I fragments of normal DNA are not seen in HPFH-1 DNA, whereas 13.0-kilobase *Bam*HI and 13.0-kilobase *Hpa*I fragments are observed (Fig. 6a-c). Thus, the deletion in HPFH-1 DNA, which terminates near the RI H fragment, has an identical effect on the size of restriction enzyme fragments detected by either the RI H or  $\gamma$ -gene probes. These results definitely establish physical linkage between the 3'- $\gamma$ -gene and the RI H fragment.

We have previously shown that the RI H fragment is linked to the 5' end of the  $\delta$ -globin gene in cloned genomic DNA<sup>19</sup>. The linkage of the 3'- $\gamma$ -gene with the RI H fragment described here, and the linkage of the RI H fragment with the 5'- $\delta$ -gene previously described provide unambiguous proof for the linkage arrangement shown in Fig. 1a. Consistent with this conclusion, we have observed that a 15.5-kilobase *Bam*HI fragment also hybridises with the  $\beta$ -globin probe (Fig. 6d) in conditions in which cross-hybridisation of  $\gamma$ -gene sequences with the  $\beta$ -globin probe is not observed (compare Fig. 6b and d). The  $\beta$ -like globin genes are therefore arranged in the order: 5'- $\gamma$ - $\gamma$ - $\delta$ - $\beta$ 3'.

## Discussion

We have used the detailed map of restriction endonuclease cleavage sites within and surrounding the  $\delta$ - and  $\beta$ -globin genes to locate the end points of deletions in the DNA from individuals with  $\delta\beta$ -thalassaemia and HPFH we have designated  $\delta\beta$ -1 and HPFH-1 and 2. The deletions in HPFH-1 and 2 are indistinguishable. In addition, the haematological findings in the two cases are virtually identical<sup>3,4,11,12</sup>. Although there is no known family relationship between the HPFH-1 and 2 individuals, it is possible that the HPFH chromosomes in the two cases had the same ultimate origin. Alternatively, it is possible that the end point of the deletions represents a mutational hot spot so that the two deletions were in fact the products of independent events.

The haematological findings in the  $\delta\beta$ -1 and HPFH-1 and 2 cases reveal several significant differences<sup>3,4,11,12,22</sup>. In  $\delta\beta$ -1, characteristics of thalassaemia which include anaemia and hypochromic, microcytic red cells were observed. In addition, analysis of heterozygous relatives indicated that 10% of their haemoglobin was HbF containing both  $\gamma$ - and  $\delta$ -polypeptide chains and the cellular distribution was heterogeneous (30–40% of the cells stain for HbF). In HPFH-1 and 2 none of the characteristics of thalassaemia was observed. In heterozygous relatives approximately 20–30% of the haemoglobin was HbF (both  $\gamma$ - and  $\delta$ -) and the cellular distribution was homogeneous (100% of the cells stain for HbF). The high levels of HbF found in  $\delta\beta$ -thalassaemia heterozygotes may be due in part to the increased proliferation or selective survival of a small population (1%) of 'F-cells' found in the blood of normal individuals<sup>4</sup>. This is not a general phenomenon, however, as in heterozygous  $\beta^0$ -thalassaemia, which in most cases is a non-deletion type of  $\beta$ -globin deficiency<sup>9</sup>, very little HbF is found in adults. In fact, homozygous  $\beta^0$ -thalassaemia is a much more severe type of anaemia than homozygous  $\delta\beta$ -thalassaemia.

**Fig. 5** Hybridisation of normal and  $\delta\beta$ -2 DNAs with the cloned  $\gamma$ -globin cDNA plasmid and with the Xba  $\gamma$  fragment. Normal and  $\delta\beta$ -2 DNAs were hybridised as in Fig. 2 with the *in vitro* labelled *Hha*I fragment of pJW151 DNA<sup>25</sup> or the Xba  $\gamma$  fragment. The Xba  $\gamma$  fragment was isolated following *Xba*I digestion of H $\gamma$ G1, a clone of human DNA containing the  $\gamma$ - and  $\delta$ -globin genes (unpublished results). The Xba  $\gamma$  fragment contains the DNA sequences between *Xba*I sites located at similar positions in the intervening sequence of the  $\gamma$ - and  $\delta$ -genes (Fig. 1a). a, *Bgl*II, *Eco*RI digests using the  $\gamma$  probe; b, *Bam*HI, *Sac*I single and double digests using the  $\gamma$  probe; c, *Eco*RI lanes from a reprobed with the Xba  $\gamma$  fragment.

Thus, there seems to be a correlation between the extent of the deletion of the  $\delta$ - and  $\beta$ -globin genes and the level of  $\gamma$ -globin gene expression in adults, suggesting that sequences involved in the suppression of  $\gamma$ -gene expression are located in the  $\delta$ - $\beta$ -globin gene region. This deletion model for  $\gamma$ -gene expression in adults was first elaborated by Huisman *et al.*<sup>7</sup>. A comparison of the deletions in HPFH-1 and 2 and  $\delta\beta$ -1 suggests that one such regulatory sequence may be located within a 4-kilobase region on the 5' side of the  $\delta$ -globin gene. An alternative possibility is that HPFH-1 and 2 are double mutants, the second lesion affecting a negative regulatory sequence located in the  $\gamma$ -globin gene region<sup>3</sup>. Our data rule out the presence of a large deletion of sequences surrounding the  $\gamma$ -genes, but a small deletion or point mutation would not have been detected. Although the occurrence of a second mutation in all the different types of HPFH described seems unlikely, the double mutation hypothesis remains a formal possibility. Furthermore, the possibility that the HPFH phenotype results from the deletion of sequences 3' to the  $\beta$ -globin gene cannot be ruled out by our data since we have not located the rightward end points of the various deletions. However, the fact that individuals with Hb Kenya express the HPFH phenotype argues against this possibility. In Hb Kenya the region between  $\gamma$  and  $\delta$  genes is thought to be missing but the sequences which lie to the 3' side of the  $\beta$  gene are presumed to be intact<sup>7</sup>.

If there are regulatory sequences surrounding the  $\delta$ - and  $\beta$ -globin genes, what is the nature of their action? Analysis of heterozygous cases of HPFH in which only one of the  $\gamma$ -globin chains is expressed in adults have led to the suggestion that the HPFH deletion affects  $\gamma$ -gene expression *in cis*. For example, in heterozygotes of  $\gamma$ -HPFH, only the  $\gamma$ -polypeptide is detected in adults even though the  $\delta$ -chain on the normal chromosome is functional (the  $\delta$ -polypeptide is detected at birth in individuals with  $\gamma$ -HPFH but disappears during postnatal development)<sup>33</sup>. If the regulatory sequence acted *in trans*, sequences on the normal chromosome would suppress the expression of both  $\gamma$ -genes in the heterozygote. An analogous argument can be made for the heterozygous  $\gamma$ - $\delta$ -types of HPFH. If, indeed, a

*cis*-acting regulatory sequence is present in  $\delta\beta$ -1 but absent in HPFH-1 and 2 DNAs, its location, 12 kilobases to the 3' side of the  $\gamma$ -gene (Fig. 1), is unprecedented. We know of no example of a 3'-*cis* acting control sequence in either a prokaryotic or eukaryotic gene system. However, it is reasonable to suppose that sequences which lie to the 3' side of a gene could function in globin RNA processing or splicing<sup>34</sup>, in the activation of a chromosome region similar to the phenomenon of puffing in *Drosophila* polytene chromosomes<sup>35</sup>, or in an immunoglobulin-type rearrangement of DNA sequences during development<sup>36</sup>. The availability of cloned segments of DNA covering the entire  $\beta$ -like globin gene locus will make it feasible to test these possibilities.

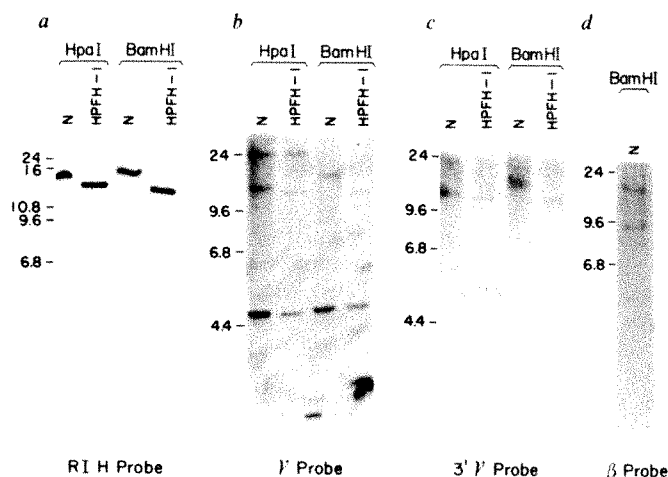

The correlation of the haematological data of the  $\delta\beta$ -2 case with the deletion map of Fig. 1 seems to argue against the existence of a negative regulatory sequence on the 5' end of the  $\delta$ -globin gene. Clinical data reveal a moderately severe anaemia which includes marked disorders in red cell morphology. The heterozygous parents of  $\delta\beta$ -2, who are first cousins, have 10–13% HbF which is non-uniformly distributed. Although peptide analysis of the HbF in  $\delta\beta$ -2 has not been reported, our data show that only the  $\gamma$ -chain could be produced. Thus,  $\delta\beta$ -2 seems to be an example of  $\gamma\delta$ -thalassaemia. However, the deletion model would predict an HPFH phenotype as the putative regulatory sequence located near the 5' end of the  $\delta$ -globin gene is missing in  $\delta\beta$ -2 DNA. This discrepancy might be explained by the fact that the deletion in  $\delta\beta$ -2 DNA extends through the  $\gamma$ -gene and into the region between the  $\gamma$  and  $\delta$ -genes. Only one case each of homozygous  $\gamma$ -HPFH<sup>37,38</sup> and  $\gamma\delta$ -thalassaemia<sup>10</sup> ( $\delta\beta$ -2) has been reported. These individuals were designated HPFH or  $\delta\beta$ -thalassaemia on the basis of analysis of heterozygous relatives even though both homozygotes displayed many of the characteristics of  $\delta\beta$ -thalassaemia. Altay *et al.* have previously discussed<sup>8</sup> the difficulty in discriminating between  $\gamma$ -types of HPFH and  $\delta\beta$ -thalassaemia. Even if  $\gamma$ -gene suppression was eliminated in  $\gamma$ -HPFH, a chain

imbalance resulting from the deletion of the  $\gamma$ -gene and surrounding sequences would result in thalassaemia traits. Thus, it may not be valid to compare  $\gamma$ - and  $\gamma\delta$ -types of HPFH. Until further information regarding the locations of deletions in cases of  $\gamma$ -HPFH and  $\delta\beta$ -thalassaemia can be obtained, the significance of the  $\delta\beta$ -2 result with regard to the deletion model cannot be assessed.

The experiments described here represent an initial step towards localising sequences which are involved in controlling the switch from fetal to adult  $\beta$ -like globin gene expression in man. The construction of a detailed linkage map of the  $\beta$ -like globin genes and the use of cloned hybridisation probes which span the entire region have established the feasibility of mapping deletions in human DNA. Hopefully, a similar analysis of additional cases of HPFH and  $\delta\beta$ -thalassaemia will ultimately lead to the identification of sequences which are involved in controlling these developmentally regulated genes.

We thank Dr Bernard Forget for human DNA samples and helpful discussions, Catherine O'Connell for preparing the *Pst* and RI H subclones, Stuart Orkin for providing  $\delta\beta$ -2 DNA, H. Lazarus for providing transformed lymphocytes from the HPFH-1 case, S. Charache for providing peripheral blood from the HPFH-2 case, Walter Schroeder for useful discussions, and P. Little, R. Flavell and R. Williamson for communicating their results before publication. This work was supported by a grant from the NIH to T.M. and by funds from a Biomedical Research Support Grant to the California Institute of Technology. R.M.L. and E.F.F. were supported by postdoctoral fellowships from the American Cancer Society and the Damon Runyon-Walter Winchell Cancer Fund, respectively. T.M. is a recipient of a Rita Allen Foundation Career Development Award.

Received 5 March; accepted 30 April 1979.

**Fig. 6** Hybridisation of normal and HPFH-1 DNA with cloned  $\beta$ - and  $\gamma$ -globin cDNA and the RI H fragment—linkage of fetal and adult  $\beta$ -like globin genes. Normal and HPFH-1 DNAs were hybridised as described in the legend to Fig. 2 with the hybridisation probes indicated below each panel. 5'- and 3'- $\gamma$ -globin specific DNA was prepared by digesting pJW151 DNA<sup>25</sup> with *Hha*I and *Bam*HI and purifying the fragments containing  $\gamma$ -globin sequences 5' and 3' to the intragenic *Bam*HI site. The 3'- $\gamma$ -globin specific DNA was labelled *in vitro* by nick translation<sup>27</sup>. A threefold excess of unlabelled 5'- $\gamma$ -globin specific DNA was included in the hybridisation as competing DNA. The remaining hybridisation probes have been described (see Figs. 2 and 3 legends). Multimeric forms of  $\Phi$ X174 DNA were included in the gel as size markers<sup>19</sup>. *a*, *Hpa*I and *Bam*HI digests using the RI H probe; *b*, *Hpa*I and *Bam*HI digests using the  $\gamma$  probe; *c*, *Hpa*I and *Bam*HI digests using the 3'- $\gamma$  probe; *d*, *Bam*HI digest using the  $\beta$  probe.

Transplantation Laboratory, and Department of Pathology, University of Helsinki

*During biosynthesis of glycophorin A in K562 cells a precursor is rapidly transferred through the endoplasmic reticulum membrane with the COOH-terminal remaining in the cytoplasm. This is glycosylated within the cell and appears at the cell surface after about 30 min. The biosynthetic pathway resembles that described for viral membrane glycoproteins.*

MOST, if not all, surface proteins of mammalian cells are glycoproteins<sup>1,2</sup>. Their peptide portions often span the lipid bilayer membrane<sup>3,4</sup> and their carbohydrate is exposed to the external milieu<sup>5-7</sup>. The biosynthetic assembly of the peptide and sugar portions and the mechanisms leading to the appropriate membrane disposition of these proteins raise intriguing questions.

Studies on virus-coded proteins have provided us with most of our more detailed knowledge of integral membrane protein biosynthesis. The polypeptides are synthesised on membrane-bound ribosomes and transferred as nascent chains through the endoplasmic reticulum membrane; glycosylation takes place on the luminal side<sup>8-10</sup>. The attachment of the core portions of the oligosaccharides may occur, through lipid-linked intermediates, even before the polypeptide chains have been completely synthesised. As the virus proteins use the host cell machinery for their biosynthesis, similar mechanisms may be anticipated for mammalian surface proteins.

Most of our information on cell membrane structure is derived from studies on the easily available human erythrocyte membrane<sup>2,13,14</sup>. Its major sialic acid-rich glycoprotein, glycophorin A (refs 15, 16), is the best characterised integral membrane protein. Glycophorin A spans the membrane with its NH<sub>2</sub>-terminus on the outside and its COOH-terminus in the cytoplasm<sup>3,4</sup>, and has a molecular weight (MW) of 31,000. On polyacrylamide gel electrophoresis in the presence of SDS it shows a higher apparent MW because of its 60% carbohydrate content<sup>3,17</sup>. Determination of its amino acid sequence<sup>18,19</sup> indicates that it has 15 serine/threonine-linked oligosaccharides and one asparagine-linked complex oligosaccharide on the external surface of the erythrocyte.

We have produced specific anti-glycophorin A antiserum<sup>20</sup> by immunising rabbits with a crude preparation of glycophorin followed by absorption with En(a-) red cell membranes, which lack glycophorin<sup>16,21-23</sup>. The availability of this specific reagent for glycophorin A and our extensive knowledge of the molecular structure of this glycoprotein provide a potentially useful system for elucidating the pathways involved in mammalian plasma membrane glycoprotein biosynthesis.

We have previously observed that the human continuous leukaemia cell line K562 (ref. 24) is erythroid, and synthesises and expresses glycophorin A on its surface<sup>25,26</sup>. In this report we

outline the biosynthesis of glycophorin A from a precursor form, its insertion into the endoplasmic reticulum membrane, its subsequent glycosylation and its migration to the plasma membrane.

## Identification of a precursor for glycophorin A

For studies on the biosynthesis of glycophorin A, K562 cells were labelled with <sup>35</sup>S-methionine for 5 min and chased with medium containing non-radioactive methionine. The labelled cells were solubilised in buffer containing Triton X-100 and immune precipitation was carried out with anti-glycophorin A antiserum or control serum and protein A-containing staphylococci<sup>20</sup>. The precipitates were analysed by polyacrylamide slab gel electrophoresis in the presence of SDS followed by fluorography. After 5 min of labelling a single protein was specifically precipitated. It had an apparent MW of 37,000 and was designated GP<sub>a</sub> (Fig. 1a, B). The use of internal labelling meant that a high background radioactivity could not be avoided and therefore the appearance of the specifically precipitated protein could only be followed by using controls with preimmunisation serum. When chased for 10 min (Fig. 1a, D) the final glycophorin A molecule (designated GP<sub>c</sub>), with an apparent MW of 39,000, became visible, and its concentration relative to that of GP<sub>a</sub> increased during chase for 25–60 min (Fig. 1a, F–J).

## Appearance of glycophorin A at the cell surface

As surface-exposed glycophorin A can be cleaved by trypsin<sup>15,26</sup> the time course of its externalisation was followed by trypsin treatment of labelled intact cells. After labelling for 5 min followed by chase for 10 min, neither the precursor protein, GP<sub>a</sub>, nor the completed glycophorin A (GP<sub>c</sub>) had reached the cell surface, as indicated by their insensitivity to trypsinisation (Fig. 1b, E, G). After 25 and 45 min chase no GP<sub>c</sub> was seen in trypsin-treated cells, but GP<sub>a</sub> was still detected (Fig. 1b, I, K). In the absence of trypsin treatment the GP<sub>c</sub> band was stronger than the GP<sub>a</sub> band at these time points (compare Fig. 1a, F, H). This shows that after 25 min glycophorin A had appeared at the cell surface but that GP<sub>a</sub> had not become exposed.

## Glycophorin A precursor is incompletely glycosylated

We followed the sequence of glycosylation using lectin columns of known specificity. The glycophorin A precursor, GP<sub>a</sub>, already contained glucose/mannose-like residues because it bound to lentil lectin-Sepharose and could be eluted with  $\alpha$ -methylmannoside (Fig. 2B). However, the following results indicate that GP<sub>a</sub> does not contain significant amounts of galactose or

**Fig. 1** *a*, Fluorography of a polyacrylamide slab gel of immune precipitates obtained from pulse-chased  $^{35}\text{S}$ -methionine-labelled K562 cells with anti-glycophorin A antiserum and control serum. K562 cells ( $80 \times 10^6$ ) were grown in RPMI-1640 culture medium (GIBCO) containing 10% newborn calf serum. After washing three times with 0.15 M NaCl and 0.01 M sodium phosphate, pH 7.4 (PBS), at  $37^\circ\text{C}$ , the cells were suspended in 5 ml of methionine-free Eagle's minimal essential medium (MEM) containing 0.2% bovine serum albumin (Sigma). The cells were incubated with gentle shaking in a  $\text{CO}_2$ -atmosphere for 30 min at  $37^\circ\text{C}$  and 1.2 mCi of  $^{35}\text{S}$ -methionine (Radiochemical Centre, 1,130 Ci mmol $^{-1}$ ) added. After 5 min 1 ml of the suspension was withdrawn to ice-cold PBS and the cells immediately washed three times with PBS at  $0^\circ\text{C}$ . The rest of the pulse-labelled cells were rapidly washed at  $37^\circ\text{C}$  with MEM containing a 50-fold excess of cold methionine and suspended in 4 ml of this medium. After incubation for 10, 25, 45 and 60 min 1-ml aliquots were removed and the cells washed at  $0^\circ\text{C}$  as above. All washed cell samples were then suspended in 4 ml of PBS at  $0^\circ\text{C}$  and 1 ml from each taken for trypsinisation (see *b* below). The rest of the samples were centrifuged and the cells dissolved at  $0^\circ\text{C}$  in PBS containing 1% Triton X-100, 1% ethanol and 2 mM phenylmethylsulphonylfluoride (Sigma) as a protease inhibitor (buffer A). Aliquots of the Triton X-100 extracts were taken for immune precipitation experiments using 5  $\mu\text{l}$  anti-glycophorin A antiserum or control serum and the *Staphylococcus aureus* protein A technique as described in detail previously $^{20,26}$ . The immune precipitates were studied by polyacrylamide slab gel electrophoresis in the presence of SDS $^{34}$  using a 12% acrylamide concentration in the separating gel. The treatment of the slab gels for fluorography $^{35}$  and the  $^{14}\text{C}$ -labelled $^{36}$  standard proteins have been described earlier $^{27}$ . A,  $^{14}\text{C}$ -labelled standard proteins: TH = thyroglobulin; TR = transferrin; HA = human albumin; OV = ovalbumin; B, immune precipitate obtained with anti-glycophorin A antiserum from K562 cells labelled for 5 min with  $^{35}\text{S}$ -methionine; C, with preimmune serum; D, immune precipitate obtained with antiserum from cells labelled for 5 min with  $^{35}\text{S}$ -methionine followed by chase for 10 min; E, with preimmune serum; F, immune precipitate obtained with antiserum from cells after 25 min chase; G, with preimmune serum; H, immune precipitate obtained with antiserum from cells after 45 min chase; I, with preimmune serum; J, immune precipitate obtained with antiserum from cells after 60 min chase; K, with preimmune serum. *b*, Fluorography of a polyacrylamide slab gel of labelled erythrocyte membranes and immune precipitates obtained from trypsin-treated K562 cells labelled with  $^{35}\text{S}$ -methionine. Part of the  $^{35}\text{S}$ -methionine-labelled cells obtained from the experiment described for *a* were treated with 0.1 mg ml $^{-1}$  trypsin (Merck, Darmstadt) for 10 min at  $37^\circ\text{C}$ . The samples were then immediately washed with PBS at  $0^\circ\text{C}$  and solubilised in buffer A. Immune precipitations and polyacrylamide slab gel electrophoresis were carried out as described in *a*. A,  $^{14}\text{C}$ -labelled standard proteins (same as in *a*); B, surface glycoprotein pattern of erythrocyte membranes labelled with  $^3\text{H}$  after treatment of erythrocytes with neuraminidase and galactose oxidase followed by  $\text{NaB}^3\text{H}_4$  (ref. 6); C, surface glycoprotein pattern of erythrocyte membranes obtained after labelling erythrocytes by the periodate/ $\text{NaB}^3\text{H}_4$  method $^{27}$ ; PAS 2 = predominantly glycophorin A monomer; D, surface glycoprotein pattern of periodate/ $\text{NaB}^3\text{H}_4$ -labelled membranes after treatment of labelled intact erythrocytes with 0.1 mg ml $^{-1}$  trypsin for 10 min at  $37^\circ\text{C}$ ; E, immune precipitate obtained with anti-glycophorin A antiserum from trypsinised K562 cells that had been labelled with  $^{35}\text{S}$ -methionine for 5 min; F, with preimmune serum; G, immune precipitate obtained with antiserum from cells labelled for 5 min with  $^{35}\text{S}$ -methionine followed by chase for 10 min; H, with preimmune serum; I, immune precipitate with antiserum from cells after 25 min chase; J, with preimmune serum; K, immune precipitate with antiserum from cells after 45 min chase; L, with preimmune serum.

**Fig. 2** Fluorography of a polyacrylamide slab gel of glycophorin molecules bound to lentil lectin-Sepharose and the effect of neuraminidase on their electrophoretic mobilities. K562 cells were labelled with  $^{35}\text{S}$ -methionine as described in Fig. 1*a* legend, washed at  $0^\circ\text{C}$  with PBS, solubilised in buffer A and applied to lentil lectin-Sepharose columns. *Lens culinaris* lectin was prepared by affinity chromatography $^{38}$  and coupled to CNBr-activated Sepharose 4B as described in detail previously $^{37}$ . The material eluted with 0.1 M  $\alpha$ -methyl mannoside (Calbiochem) was pooled and concentrated by vacuum dialysis to 3 ml. To 1-ml aliquots from each sample was added 0.3 ml of Dulbecco's PBS containing  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  and 100 units of *Vibrio cholerae* neuraminidase (Behringwerke). The neuraminidase preparation did not contain proteolytic activity when assayed as described previously $^6$ . Two other identical aliquots did not receive neuraminidase. All samples were incubated for 10 min at  $37^\circ\text{C}$ . After incubation one control sample and the neuraminidase-treated sample were incubated with 5  $\mu\text{l}$  anti-glycophorin A antiserum and the third tube with preimmune serum followed by protein A-containing staphylococci. The immune precipitates were then analysed by polyacrylamide slab gel electrophoresis as described above. A, surface glycoprotein pattern of periodate/ $\text{NaB}^3\text{H}_4$ -labelled erythrocyte membranes; B, immune precipitate obtained with anti-glycophorin A antiserum from the glycoprotein fraction of K562 cells labelled for 5 min with  $^{35}\text{S}$ -methionine; C, immune precipitate with antiserum from the neuraminidase-treated glycoprotein fraction of cells labelled for 5 min; D, with preimmune serum; E, immune precipitate obtained with antiserum from the glycoprotein fraction of cells labelled for 5 min followed by 10 min chase; F, immune precipitate with antiserum from the neuraminidase-treated glycoprotein fraction of cells labelled for 5 min followed by 10 min chase; G, with preimmune serum; H, immune precipitate obtained with antiserum after 25 min chase; I, immune precipitate with antiserum of the 25-min chase sample treated with neuraminidase; J, with preimmune serum; K, immune precipitate obtained with antiserum after 60 min chase; L, immune precipitate with antiserum of the 60-min chase sample treated with neuraminidase; M, with preimmune serum. The corresponding scanning patterns of the glycophorin regions are shown below and were obtained with a Joyce-Loebl Chromoscan apparatus.

sialic acids. First, it did not bind to *Ricinus communis* lectin-Sepharose columns specific for  $\beta$ -D-galactose (data not shown). Second, as it is known that neuraminidase treatment of erythrocyte glycophorin A reduces its mobility on SDS-gel electrophoresis this phenomenon was used to determine the presence of sialic acids $^{27}$ . Part of the  $^{35}\text{S}$ -methionine-labelled eluates from the lentil lectin columns were treated with neuraminidase before immune precipitation.  $\text{GP}_a$  mobility on SDS-gel electrophoresis did not change after neuraminidase treatment, but instead of final glycophorin A, a molecule, designated  $\text{GP}_b$ , with an apparent MW of 41,000, was detected. This demonstrates that  $\text{GP}_c$  contains sialic acids.  $\text{GP}_c$  could be adsorbed not only to lentil lectin-Sepharose but also to *R. communis* lectin-Sepharose columns, indicating that it contains terminal  $\beta$ -D-galactosyl residues. This experiment also indicates that at this stage  $\text{GP}_a$  does not contain the penultimate galactosyl residues because its mobility would then have corresponded to that of  $\text{GP}_b$ .

### The $\text{NH}_2$ -terminal portion of glycophorin A precursor is rapidly incorporated into microsomes

The incorporation of the glycophorin A precursor into endoplasmic reticulum was studied by labelling K562 cells for 5 min with  $^{35}\text{S}$ -methionine. The labelled cells were then immediately

cooled to 0 °C, homogenised and a microsomal fraction prepared. Half of this fraction was treated with trypsin. The untreated and the trypsin-treated samples were solubilised in buffer A (see Fig. 1a legend) and passed through lentil lectin columns; the glycoproteins were eluted with  $\alpha$ -methylmannoside and immune precipitated with anti-glycophorin A antiserum. The immune precipitates from the trypsin-treated and untreated samples were electrophoresed on parallel slots of a polyacrylamide slab gel. Complete, 37,000 MW, glycophorin precursor, GP<sub>a</sub>, was recovered from untreated microsomes (Fig. 3B) but the molecule (GP<sub>at</sub>) obtained from the trypsin-treated microsomes had an apparent MW of 34,000 (Fig. 3C). This shows that a fragment of approximate MW 3,000 could be cleaved off by trypsin at this stage.

**Fig. 3** Fluorography patterns of immune precipitates from K562 microsomes analysed by polyacrylamide slab gel electrophoresis. K562 cells ( $170 \times 10^6$ ) were labelled for 5 min with  $^{35}\text{S}$ -methionine as described in Fig. 1a legend. They were then rapidly washed three times with PBS at 0 °C and suspended for 10 min in 15 ml of 10 mM KCl, 10 mM Tris and 1.5 mM  $\text{MgCl}_2$ , pH 7.4, at 0 °C. The cells were then homogenised in a tight-fitting Dounce homogeniser with 20 strokes and the nuclei removed by centrifugation at 1,000g for 10 min. The supernatant was centrifuged at 50,000g for 90 min at 4 °C in a Spinco rotor 30 and the microsomal pellet obtained suspended in 1 ml of Dulbecco's PBS. Half of this material was incubated with 0.01 mg ml<sup>-1</sup> trypsin for 10 min at 37 °C. The control sample was handled in the same way except that trypsin was omitted. After incubation 0.5 mg of soybean trypsin inhibitor (Sigma) was added to both samples. These were then dissolved in buffer A, both divided into two and immune precipitated with either 5  $\mu\text{l}$  anti-glycophorin A antiserum or preimmune serum. The immune precipitates were then analysed on a 12% polyacrylamide slab gel. A, Control microsomes + preimmune serum; B, control microsomes + anti-glycophorin A antiserum; C, trypsin-treated microsomes + anti-glycophorin A antiserum; D, trypsin-treated microsomes + preimmune serum. Note the decrease in the apparent MW of trypsin-treated GP<sub>a</sub>.

## Discussion

We recently showed that glycophorin A is expressed not only on mature red cells but also on nucleated precursor cells in human bone marrow<sup>20</sup>. This finding prompted us to look for cell lines synthesising glycophorin A. Our observation that the human continuous cell line K562 is erythroid<sup>25</sup> was the basis for the present experiments. The cells expressed  $10^6$  copies per cell of a surface glycoprotein which is indistinguishable from erythrocyte glycophorin A. The K562 protein has an apparent MW identical to that of glycophorin A from red cells, it dimerises easily—a characteristic of the erythrocyte protein—it reacts with anti-glycophorin A antiserum, contains MN blood group activity, gives rise to CNBr fragments and contains glycopeptides/oligosaccharides which closely resemble those of glycophorin A (ref. 26). Furthermore, treatment of K562 cells with sodium butyrate induces erythroid differentiation including haemoglobin synthesis and the generation of erythrocyte-like particles<sup>28</sup>.

A schematic model of the way in which we consider the biosynthesis of glycophorin A to occur is shown in Fig. 4. Three forms of glycophorin A can be recognised, GP<sub>a</sub>, GP<sub>b</sub> and GP<sub>c</sub>. GP<sub>c</sub> is the final glycophorin A molecule which is synthesised completely within the cell and is present at the cell surface after 35 min of pulse labelling. (This includes the 10 min required for trypsinisation.) This glycoprotein contains the terminal sialic acid residues and the penultimate galactosyl residues<sup>26</sup> and has

an apparent MW of 39,000 on 12% polyacrylamide gels. The presence of sialic acids gives it a higher electrophoretic mobility in the presence of SDS than after removal of these residues<sup>27</sup> (Fig. 2). GP<sub>b</sub>, which can be obtained from GP<sub>c</sub> only after neuraminidase treatment, has an apparent MW of 41,000.

GP<sub>a</sub> is obviously a precursor of glycophorin A. It reacts with anti-glycophorin A antiserum and the precursor/product relationship is evident from the pulse-chase experiments (Fig. 1a). It has an apparent MW of 37,000, does not adsorb to *R. communis* lectin-Sepharose and does not contain sialic acids (Fig. 2B,C). The 4,000 MW difference between desialylated glycophorin A (GP<sub>b</sub>) and GP<sub>a</sub> should correspond to approximately 20 monosaccharides. This cannot be accounted for solely by the completion of the complex oligosaccharide at Asn 26 but must involve the addition of galactosyl groups to the 15 alkali-labile chains. Apparently, the sialic acids are then rapidly added because a precursor form corresponding to desialylated glycophorin A (GP<sub>b</sub>) is never observed during the pulse-chase experiments. The addition of galactosyl and sialic acid residues is known to occur late in the biosynthesis of glycoproteins, mainly in Golgi membranes<sup>29</sup>.

GP<sub>a</sub> is found after 5 min of labelling in microsomes when the carbohydrate is protected from the action of trypsin (Fig. 3). Trypsin treatment decreases its apparent MW by 3,000 and the released peptide should correspond to residues 101(102)–131 of erythrocyte glycophorin A or tryptic peptide T<sub>4</sub> (ref. 19) located at the COOH-terminal end. When sealed, everted erythrocyte ghosts are treated with trypsin no reduction in the apparent MW of glycophorin A is observed<sup>30</sup>. One possibility is that proteolytic cleavage does occur, but the 3,000 MW difference is not seen because glycophorin A gives a broad and diffuse band on electrophoresis of ghosts. Another, and more likely, possibility is that the COOH-terminal portion of newly synthesised glycophorin A in microsomes is more easily accessible to proteases than the molecule in the finished erythrocyte membrane where it may be covered by other proteins. Treatment of intact cells with trypsin releases much more from the NH<sub>2</sub>-terminal end of the polypeptide in soluble form<sup>15,31</sup>. This indicates that the COOH-terminal part already in the endoplasmic reticulum has a similar location in the red cell membrane.

The biosynthetic pathway of glycophorin A corresponds well to that described for the glycoprotein (G protein) of vesicular stomatitis virus. Glycophorin A has a more complex carbohydrate composition than the viral protein, involving two types of quite different oligosaccharides. The glycosylation of glycophorin A probably involves both lipid intermediates for the synthesis of the *N*-glycosidic oligosaccharide<sup>12</sup> and direct glyco-

**Fig. 4** Our schematic view of the biosynthesis of glycophorin A. GP<sub>a</sub>, glycophorin A precursor; GP<sub>b</sub>, glycophorin A treated with neuraminidase to demonstrate the stage before addition of sialic acid residues; GP<sub>c</sub>, final glycophorin A. ● = hexosamine, ○ = neutral hexose, ▽ = sialic acid. The trypsin cleavage site of GP<sub>a</sub> in microsomes is shown. The asparagine-linked oligosaccharide located at residue 26 in the polypeptide chain is shown in GP<sub>a</sub> in an 'untrimmed' form from the structure described by Li *et al.*<sup>12</sup>.

sylation of the serine/threonine residues from UDP-*N*-acetyl-D-galactosamine<sup>32</sup>. However, similar times are required for insertion into the endoplasmic reticulum membrane, glycosylation and appearance at the cell surface. Whether glycoporphin A contains an additional NH<sub>2</sub>-terminal signal sequence found in most glycoprotein precursors<sup>33</sup> is not known and is being investigated.

We thank Anneli Asikainen, Marja Wilkman and Liisa Alajoki for assistance. K562 cells were obtained from Dr K. Nilsson. This study was supported by the Academy of Finland, the Finnish Cancer Society and Lääke Oy.

# The three-dimensional structure of tubulin protofilaments

L. A. Amos & T. S. Baker\*

MRC Laboratory of Molecular Biology, Cambridge, UK

*A three-dimensional image of tubulin protofilaments, reconstructed to 20 Å resolution from electron micrographs of negatively stained zinc-induced sheets, has been used to generate an improved model for microtubule substructure. This model has been used to phase a reconstructed image from X-ray amplitudes, which is compatible with the electron microscope results.*

THE three-dimensional structure of eukaryotic microtubules has been studied by electron microscopy (EM) of individual specimens<sup>1–4</sup> and by X-ray diffraction of oriented gels of microtubules<sup>5–7</sup>. Results from EM suggested an arrangement of monomer subunits on the same helical surface lattice for both neurotubules and flagellar microtubules<sup>2,3</sup>. Early X-ray diffraction patterns seemed to be in disagreement<sup>5</sup>, but this was resolved after further studies<sup>6,7</sup>; the X-ray data now seem to be quite consistent with the geometry determined by EM. However, there still seem to be some differences in the data, especially with respect to the shapes of the subunits, even at very low (40 Å) resolution. Even different EM studies have tended to give somewhat different impressions of the substructure. In images of brain tubulin sheets, which are thought to be the equivalent of opened-out microtubules, each tubulin subunit seemed to be split longitudinally into two separate domains<sup>2,4</sup>. This feature was not detected in a three-dimensional analysis of intact flagellar microtubules<sup>3</sup>, in which the monomers apparently consisted of single globular units, although the overall outline of the subunits was similar. Furthermore, a model based on an interpretation of the intensity distribution in X-ray diffraction patterns of brain microtubules<sup>7</sup> showed

subunit shapes which were incompatible with either of the classes of image obtained by EM. We now present a new model of the structure of tubulin, based on three-dimensional EM image reconstruction of extended brain tubulin sheets, which seems to explain the differences between the earlier images and suggests a compatible interpretation of the X-ray diffraction patterns from microtubules.

## Zinc-induced tubulin sheets

The specimens we studied were the large two-dimensional crystalline arrays of brain tubulin which assemble in the presence of zinc ions<sup>8,9</sup>. These sheets are apparently made up of the same linear arrays of subunits, or protofilaments, as 'normal' sheets, which are often found in samples of repolymerised microtubule protein and which have been proposed as precursors in microtubule assembly<sup>2,10</sup>. Whereas normal sheets are usually no more than 12 protofilaments wide, presumably because a sheet of 13 protofilaments closes to form a microtubule, zinc-induced sheets may be 100 or more protofilaments wide and are therefore much better for periodic structural analysis. Studies of their projected structure have shown that protofilaments are arranged with alternating polarity (see Fig. 1a), so that these arrays have P2<sub>1</sub> crystallographic symmetry<sup>11,12</sup>. The arrangement is thus quite different from that in a microtubule or a normal sheet, where all the protofilaments have the same polarity. However, the individual protofilaments seem to be very similar, having the same 48–49 Å side-to-side spacing in both types of sheet. This common feature suggests that the rotational orientation of a protofilament about its axis is similar in both structures. By comparing the obliquity of the projected subunit shapes in Fig. 1a with those in computer-filtered EM images of normal tubulin sheets<sup>2,4</sup>, we were also able to deduce that the protofilament images labelled I in Fig. 1 represent the view from the outside of a normal microtubule<sup>11</sup>.

\* Present address: Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02154.

Figure 1a was derived from four highly selected low-dose EM images of negatively stained specimens and includes data to 16 Å resolution<sup>11</sup>. To obtain a three-dimensional image, this untitled projection was combined with 40 independent images of sheets tilted through angles of 21°, 35° or 51° about various axes<sup>14</sup>. The number of different orientations of the sheets was more than sufficient to provide homogeneous data to 20 Å resolution within the angular range covered by tilting up to 51°. The intensities of most of the reflections fell to noise level within this range. Additional data, corresponding to higher tilt angles, which could not easily be reached by tilting in the microscope, were obtained from images of negatively stained specimens embedded in plastic and sectioned normal to the sheets<sup>13</sup>. These data were to about 40 Å resolution; the complete set of data is therefore still not fully isotropic, so that density variations in the direction normal to the sheets are not quite as well resolved as those in the plane of the sheets. Full details of data collection and analysis are presented elsewhere<sup>13</sup>.

### Three-dimensional model of the sheets

The main features of the reconstructed three-dimensional density distribution are illustrated in Figs 1b and 2. Viewed down its long axis, each protofilament is roughly triangular in shape, with one corner of the triangle protruding from one side of the sheet. Thus, the two exposed surfaces of a protofilament are very different. In longitudinal view, one surface has the form of a longitudinal ridge and the other has a flat ladder-like appearance, with sloping bi-lobed rungs. If we are correct in assuming that the protofilament images labelled I in Fig. 1a represent the view from outside a microtubule, then the ridged surface must be on the outside, while the ladder-like appearance should occur on the inside surface. This is discussed in detail later.

The apparent thickness of the negatively stained sheets, as observed directly in section and also as estimated from the tilted views, is only about 45–50 Å, compared with a difference of 70–80 Å between the inner and outer radii of a microtubule, as estimated from X-ray diffraction measurements<sup>5–7</sup>. Therefore, the sheets have probably shrunk in this dimension as they dried down on to the EM support grid. It is also possible that part of the apparent reduction in thickness results from the masking of

fine surface features extending into the negative stain, or by positive staining of protein on the protofilament surface. Thus, the ridge in particular may extend out further than it seems to in the reconstructed image. The importance of such effects is discussed later.

As described previously<sup>11</sup>, each protofilament clearly consists of an alternating linear array of two kinds of slightly different subunits, believed to represent the two species of 55,000 molecular weight monomer which form the tubulin heterodimer<sup>15</sup>. Both kinds of subunit appear in projection as elongated shapes (Fig. 1a), with their long axes at about 40° to the protofilament axes. If one attempts to follow the density corresponding to an individual subunit through successive sections parallel to the central plane of the sheet (Fig. 2), the peaks move gradually downwards between the first and last sections. The subunits thus apparently have the general form of tilted ellipsoids when viewed from the side, as well as face on.

The difference between the two kinds of subunit seems to be rather less in three dimensions than in the two-dimensional projection, showing significantly only at the ladder-like inside surface of the protofilaments. The apparently more definite division into two domains of one of the two subunits presumably represents a real difference in the internal structure of the two monomers.

The pattern of interprotofilament contacts is also not as complex as suggested by the original projection (Fig. 1a), where the contacts between each pair of subunits seem to be represented by two separate regions of higher density in the interprotofilament gap<sup>11</sup>. In the three-dimensional model, the contacts seem to take place over single fairly broad zones (Fig. 2, P to Q or R to S), centred on the central plane of the sheets. The complexity in projection is due to superposition of the intricate stain distributions at the two surfaces of the sheets.

### Model protofilaments rearranged to represent a microtubule

Normal microtubules observed *in situ* consist, in most cells, of 13 longitudinal protofilaments<sup>16</sup> in a polar arrangement<sup>3</sup>. Reassembled microtubules often contain 14 protofilaments<sup>17</sup>, but these are probably aberrant structures. To simulate a normal

**Fig. 1** *a*, Computer reconstructed image of negatively stained zinc-tubulin sheets seen in projection<sup>11</sup>. The variation in density is represented by evenly spaced contour levels. Regions dominated by negative stain are shown shaded while absence of stain, corresponding to protein, is white. Neighbouring longitudinal protofilaments, each 48 Å wide, are related by P<sub>2</sub> symmetry, about screw dyad axes normal to the protofilaments and in the plane of the sheet. Each globular unit along a protofilament is thought to represent a monomer of  $\alpha$ - or  $\beta$ -tubulin. The boxes drawn on the image each enclose what seems to be an 80 Å long  $\alpha$ - $\beta$  heterodimer. *b*, A solid model of part of a zinc-tubulin sheet, with boundaries which follow one of the contour levels in Fig. 2. Two different surfaces of the protofilaments are presented, as adjacent protofilaments face different ways.

Fig. 2 Sections at different levels ( $z$ ) through one protofilament of the reconstructed three-dimensional model of the negatively stained zinc-tubulin sheets. Below each section is given its distance from the plane through the centre of the sheet. Features at the boundaries of the protofilament are labelled as in the projection in Fig. 1a.

microtubule, therefore, we have arranged 13 model zinc-tubulin protofilaments, as shown in Fig. 3. In this arrangement, the former regions of contact between subunits in the sheet seem to match up again in the tubule, although in different polar orientations<sup>11</sup>. Probably the same hydrophobic regions of each subunit are involved in the assembly of both types of structure. The model in Fig. 3 was assembled with the ridged sides of the protofilaments outermost, so that the projected subunit shapes would agree with images of negatively stained normal sheets<sup>2,4</sup>. There are several observations which support this choice of orientation. One is the good agreement between the appearance of this model and that of the three-dimensional model reconstructed from images of intact flagellar microtubules<sup>3</sup>. In particular, the deep interprotofilament grooves are features of the

outer surfaces of both models. The presence of these grooves at high radius is also strongly indicated by X-ray diffraction data<sup>5-7</sup>. If the wedge-shaped protofilaments were oriented with the ridged surface inwards, grooves would not be formed specifically at the outer surface; the interprotofilament contrast would be weaker and roughly equal at all radii between 70 and 150 Å. Clear images of sectioned normal microtubules<sup>17,18</sup> also support the conclusion that the protofilaments should appear in cross-section as outwardly pointing wedge shapes. A final observation which indicates that, in a normal microtubule, interprotofilament contact is limited to inner radii (less than 110 Å) is that the spacing of protofilaments in flat sheets (normal or zinc-induced) is consistently less (48–49 Å) than the spacing of 53 Å at the mean radius (110 Å) of a microtubule.

Fig. 3 a, Models of zinc-tubulin protofilaments from the reconstructed image shown in Fig. 1b, rearranged to conform to the helical symmetry established for a normal microtubule. Thus, the monomer subunits lie on a family of three shallow left-handed helices. The relative arrangement of tubulin dimers is that observed in complete flagellar microtubules<sup>3</sup> (see text). Two unit cells, each enclosing an 80-Å long  $\alpha$ - $\beta$  dimer, are outlined. b, Inside surface of part of a microtubule, opened out to form a 'normal' sheet. The polar arrangement of the protofilaments is the same as in a. Comparison of these images with the

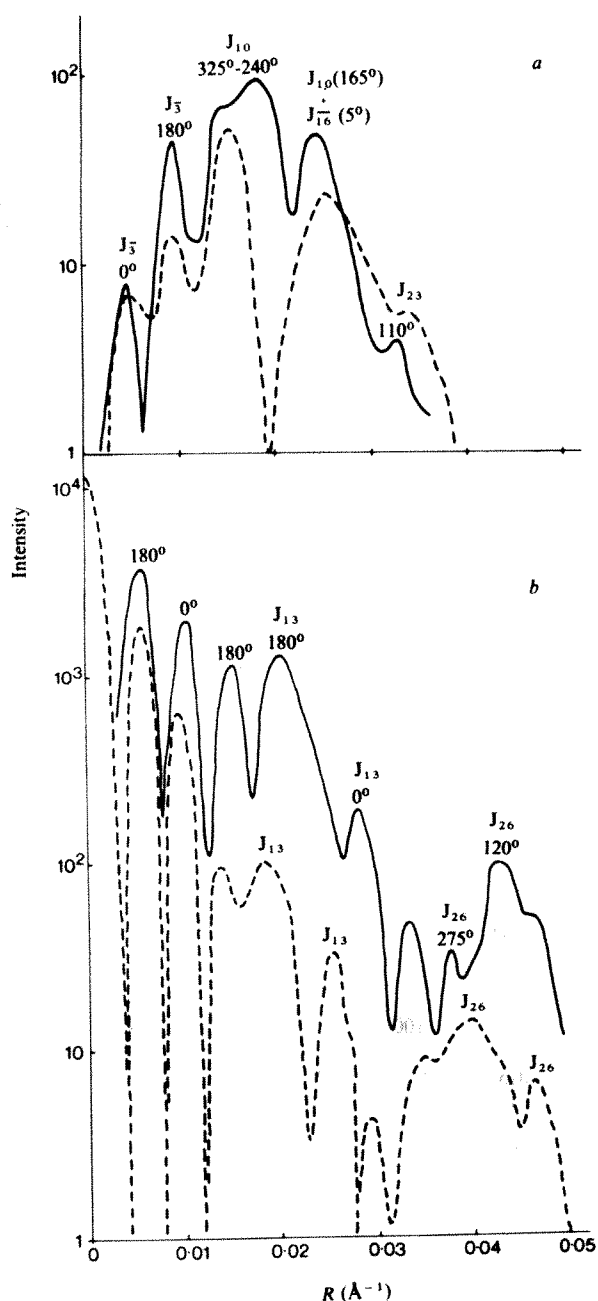

reconstructed three-dimensional model of intact flagellar microtubules<sup>3</sup>, suggests that the bottom of the model, as shown in these two views, corresponds to the basal end of a flagellar microtubule.

The other assumption incorporated in the model shown in Fig. 3 is that the subunit dimers in adjacent protofilaments are in a staggered arrangement, as observed in complete flagellar microtubules, that is, the A-tubules of outer doublet microtubules<sup>3</sup> and the central singlet microtubules<sup>1</sup>. This is in fact the only helically symmetrical arrangement possible for a 13-protofilament microtubule in which the monomer subunits are arranged as shown. There is some evidence<sup>7,12</sup> that brain tubulin may sometimes reassemble *in vitro* in an alternative arrangement similar to that in a flagellar B-tubule<sup>3</sup>, but when microtubules are reassembled from brain extracts containing a full complement of so-called microtubule associated proteins, the latter, seen as projections from the outsides of the tubules, seem to follow the symmetry of the A-tubule lattice<sup>19</sup>. This point is discussed in more detail elsewhere<sup>20</sup>.

### Variations in EM images

It is now understandable why somewhat variable images have been obtained in previous EM studies of protofilament structure. The appearance seems to vary according to which of the two different protofilament surfaces is the more strongly

emphasised by the negative stain. The bi-lobed, or ladder-like appearance obtained for opened-out brain microtubules<sup>2,3</sup> corresponds rather closely to the appearance of the inner surface of the present model. Erickson<sup>2</sup> noted that the normal sheets, being curved in solution, always fell with the outer surface next to the carbon substrate of the EM grid. Presumably the inside surface, which was thereby most exposed to the negative stain subsequently applied to the grid, was more strongly contrasted than the outer surface. The outer surface of the three-dimensional image reconstructed from images of intact flagellar microtubules<sup>3</sup>, on the other hand, closely resembles the outer surfaces of the protofilaments in the present model, whereas the inner surface showed much less detail. In the case of an intact microtubule, it seems that the outside is most strongly contrasted by negative stain. In the zinc-induced sheets the orientation of the protofilaments alternates. Differential staining of the two sides of such sheets probably explains the great difference in projection of adjacent protofilaments observed initially by Crepeau *et al.*<sup>4</sup>. However, the images we have used all show very good P2, symmetry<sup>11</sup>, so we deduce that in our specimens each protofilament must be more or less equally well contrasted on both sides. The three-dimensional image reconstructed from

**Fig. 4** Intensity distributions for the equatorial (b) and 40 Å (a) layer lines of diffraction patterns from real and model microtubules. The dashed lines represent the intensity distributions measured by Mandelkow *et al.*<sup>7</sup> in X-ray diffraction patterns obtained from oriented hydrated gels of microtubules. The solid lines follow cylindrically averaged intensity distributions calculated for a model microtubule, consisting of 13 zinc-tubulin protofilament images arranged on a mean radius of 110 Å; the density distributions were uniformly 'stretched' by 30% in the direction normal to the zinc-tubulin sheets, to correspond more closely to the microtubule dimensions estimated from X-ray diffraction data<sup>7</sup> (see text). The only significant effect of this is a slight change in the radial positions of the intensity peaks in the calculated diffraction pattern. The relative phases (for protein represented as positive density) determined for the various helical contributions are indicated above the intensity peaks. On the calculated equator, the strong peaks near the origin represent the transform of a hollow cylinder. The peaks at 0.020 Å<sup>-1</sup> and 0.028 Å<sup>-1</sup> (labelled J<sub>13</sub>) arise mainly from the division of the cylinder into 13 distinct longitudinal protofilaments: the first is from 13-fold contrast at the outside of the cylinder, the second from the much weaker contrast on the inside. Second order diffraction from the protofilaments provides the main contributions to the last group of peaks (J<sub>26</sub>): the weak inner peak of this group corresponds to features of the outside of the cylinder, the stronger peak to the inner side. On the 40 Å or second layer line (based on an axial repeat of 80 Å) of the calculated diffraction pattern, the two (J<sub>-3</sub>) peaks close to the meridian arise from outer and inner radii contributions from the family of three shallow left-handed helices; the apparently double third peak (J<sub>10</sub>) (with varying phase across it) consists mainly of contributions from the 10 steeper, right handed helices at outer radii. The broad fourth peak includes a small contribution from the latter family at inner radius, but also significant contributions from the left-handed 16-member family at radii centred on a mean of about 110 Å. The calculated curves do not correspond exactly with those measured from X-ray diffraction patterns; for example, the relative intensities on the equator fall off differently and the J<sub>10</sub> peak on the 40 Å layer line has a different shape. However, some differences are to be expected, as the model was derived by studying dehydrated protein embedded in metal stain, whereas the X-ray diffraction pattern is from hydrated unstained specimens and provides information about the contrast between protein and aqueous solvent.

them should therefore provide a more reliable impression of the structure than has been obtained from previous EM studies of tubulin structure.

However, because of artefacts due to dehydration, radiation damage and the limitations of negative stain contrast, the results obtained by EM are not wholly satisfactory for studying the native structure of proteins. Low-dose electron microscopy of unstained specimens, embedded in glucose or sucrose solutions to alleviate the effects of dehydration, has proved successful in studies of the substructure of certain thin two-dimensional crystals of biological origin<sup>14,21</sup>. However, the results obtained so far with tubulin sheets<sup>4</sup> have not been very promising, the resolution attained being somewhat less than that obtained from negatively stained specimens. The zinc-tubulin sheets, although they grow much larger than normal tubulin sheets, probably still do not allow sufficient averaging to compensate for the extremely low signal-to-noise ratio in EM images of unstained protein.

### Diffraction patterns from microtubules

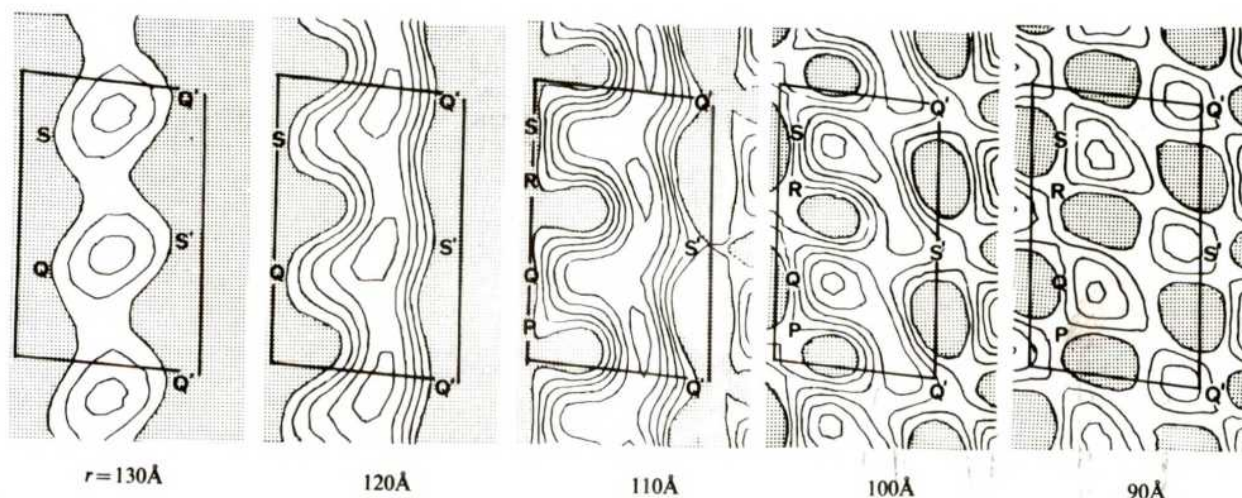

X-ray diffraction of oriented gels of hydrated microtubules provides information about the protein in its native state, but the X-ray patterns from native specimens do not provide sufficient data by themselves for the reconstruction of a three-dimensional image of the structure. One way of trying to supply the missing information at low resolution is to use phase information obtained by electron microscopy<sup>7</sup>. For this purpose, we have calculated a three-dimensional diffraction pattern for the model density distribution shown in Fig. 3. The calculated diffracted intensity distributions, averaged around the vertical axis to simulate diffraction from an oriented gel of microtubules, are shown in Fig. 4 for the equatorial and 40 Å layer lines, together with the corresponding relative intensities measured from X-ray diffraction patterns. These curves calculated for the rearranged zinc-tubulin protofilaments are surprisingly more similar to the X-ray curves than are the distributions obtained directly from optical diffraction patterns of negatively stained microtubules<sup>1-4,7</sup>. In the latter case, the peak closest to the meridian on the 40 Å layer line is usually the strongest on that

layer line, a peak corresponding to the third peak on the X-ray 40 Å layer line is much weaker in the microtubule optical diffraction patterns and the other two X-ray peaks are absent. As discussed above, this seems to be because negative stain does not map out the surface of a protofilament in an intact microtubule as closely as it does that of a protofilament in a zinc-tubulin sheet.

### Interpreting the X-ray patterns

Cohen *et al.*<sup>6,7</sup> have interpreted the low angle X-ray intensity distribution (Fig. 4, dashed lines) in terms of diffraction mainly from the inner and outer surfaces of the microtubules, which apparently have inner and outer radii of 70 and 150 Å respectively. The strong equatorial  $J_{13}$  and  $J_{26}$  reflections have both been identified as coming from the outer surface, with mean radii of 126 and 115 Å respectively. The series of four peaks on the 40 Å layer line were indexed as two  $J_{-3}$  contributions from outer and inner mean radii of 130 and 70 Å, followed by two  $J_{10}$  contributions from outer and inner mean radii of 120 and 70 Å.

Mandelkow *et al.*<sup>7</sup> attempted to reconstruct a three-dimensional model of a microtubule from the measured X-ray intensities, interpreted in the above manner, by combining them with phases determined by Erickson<sup>2</sup>, and confirmed by their own observations, from two-dimensional EM images of microtubules opened out as sheets. (In calculated diffraction patterns from digitised images, with a phase origin equivalent to that used in Fig. 4, phases of 180° are found for each of the lattice points corresponding to single  $J_{13}$ ,  $J_{26}$ ,  $J_{-3}$  and  $J_{10}$  contributions.) However, as the relative intensities in the X-ray diffraction pattern and the diffraction patterns from the original EM images were very different, the hybrid reconstructed image<sup>7</sup> was also quite different from the original images, with elongated subunits sloping in the opposite direction. Without reasonable agreement between the two techniques, there is no justification for combining EM phases with X-ray amplitudes. It is now possible, however, from our analysis of the zinc-tubulin structure, to suggest some modifications to the above interpretation and phasing of the X-ray patterns, which lead to a much closer consistency between the X-ray and EM data.

**Fig. 5** Sections at different radii ( $r$ ) through part of the reconstructed density distribution, calculated using Fourier amplitudes deduced from X-ray diffraction patterns of intact brain microtubules and phases (see Fig. 4) derived from model zinc-tubulin protofilaments rearranged as shown in Fig. 3. Features of the protofilament outline, which seem to correspond to those in the sections through the original image (Fig. 2), are labelled P to S. The two images are rather different at smaller radii; the sloping regions of high density (S to S') and (Q to Q') have a steeper slope than the corresponding regions in Fig. 2. (This difference seems to be less for one type of subunit in Fig. 2 than for the other.) As well as the equatorial and second (40 Å) layer lines shown in Fig. 4, the data included weak contributions from the third and fourth layer lines, estimated from the published X-ray patterns<sup>7</sup>. (Note that the indexing of the odd layer lines is determined by the arrangement of 80 Å long tubulin dimers, which is discussed below Fig. 3.) On the third layer line, an apparent  $J_2$  contribution to the X-ray diffraction patterns was included with a phase of 45° but being weak has very little effect. The fourth layer line data consisted of approximately equal  $J_{-6}$  and  $J_7$  contributions with phases of 210° and 50°, based on the model calculations.

The main difference from the previous interpretation is the source of the fourth peak from the meridian on the 40 Å layer line. Calculations from our model suggest it is probably a mixture of different contributions. As well as a small  $J_{10}$  contribution, it is likely to include a major  $J_{-16}$  contribution, with a mean radius of about 110 Å. It is not completely clear why a  $J_{-16}$  contribution is never observed in optical diffraction patterns from negatively stained microtubules or normal tubulin sheets, but it is probably for the same reason that the  $J_{10}$  contribution is weaker than the  $J_{-3}$  contribution, instead of stronger as in the X-ray patterns. The  $J_{-3}$  reflections clearly do come from the innermost and outermost surfaces of the structure and must be relatively easily revealed by negative stain, provided the surface in question is exposed to it. On the other hand, according to the present interpretation of the X-ray data, both the major  $J_{10}$  and  $J_{-16}$  contributions come from radii near the middle of the protein layer, into which it is presumably more difficult for the stain to penetrate. It may be relevant in this context that the X-ray diffraction patterns from dehydrated microtubules are said to be more similar to the optical diffraction patterns from electron micrographs<sup>5,6</sup>. This suggests that dehydration may cause the cleft between protofilaments to close up at inner radii and prevent features at these radii from contributing to the diffraction patterns.

### Phasing the X-ray data

The relative phases we assign to the various contributions (Fig. 4), which were derived from the model shown in Fig. 3, also differ from those used by Mandelkow *et al.*<sup>7</sup>. This is mainly because, in the images of the flat sheets which supplied their phases, contributions from different radii in the microtubules become superimposed in projection. Unless features at all radii have corresponding spatial frequencies exactly in phase, the relative phases in the transform of such a flattened sheet will not agree with a separated set of either inside or outside surface contributions.

One significant difference is in the values assigned to the equatorial  $J_{26}$  intensity peaks. In EM images, the feature giving rise to the strongest diffraction contribution of this order is the shallow longitudinal groove bisecting one surface of each protofilament. We interpret this surface as being on the inside of a microtubule. In the X-ray diffraction patterns, the strongest  $J_{26}$  contribution seems to come from a radius of about 115 Å, which is within the extent of the deep interprotofilament grooves on the outside surface of the microtubule. Mandelkow *et al.*<sup>7</sup> originally related this contribution to the apparent splitting of the protofilaments (hence the 180° relative phase they assigned to it), but we now interpret it as most likely due to the sharpness of the ridges on the outer surfaces of the protofilaments. A smaller peak further out on the equator, at  $R = 0.047 \text{ Å}^{-1}$ , probably arises from the apparent splitting of the protofilaments at inner radii.

According to this interpretation, the relative intensities of the two  $J_{26}$  contributions, from the inner and outer surfaces of the microtubules, are reversed in the X-ray diffraction patterns and the patterns calculated from the rearranged zinc-tubulin model. This could be due to artefacts of negative staining whereby the tips of the ridges on the outer surface of each protofilament might be swamped by negative stain and the outer surface  $J_{26}$  contribution thus reduced, while the shallow groove down the centre of the inside surface of the protofilament would tend to be over-emphasised by the stain, causing the inner surface  $J_{26}$  contribution to be enhanced.

### Model from combined X-ray and EM data

A test of the above interpretation of the X-ray patterns is to see whether a reconstructed image, based on the X-ray amplitudes and the phases derived from the rearranged model, resembles the results from EM alone. Figure 5 shows sections through one protofilament of such a calculated microtubule density distribution. This structure can be compared with the zinc-tubulin

image shown in Fig. 2, bearing in mind that the latter structure seems to have shrunk by 30–40% in the  $z$ -direction. There are some other differences between the two structures, as expected from the differences in the two sets of diffraction curves in Fig. 4. The sections in the region of the outside surface (around  $z = 12$ , 6 Å in Fig. 2; around  $r = 130$ , 120 Å in Fig. 5) are reasonably similar, but at inner radii there are some distinct differences. In particular, the 'rungs of the ladder' (around  $z = -18$ , -12 Å in Fig. 2; around  $r = 90$ , 100 Å in Fig. 5) seem much more steeply tilted, because of the greater strength of the  $J_{-16}$  contribution to the data, relative to the  $J_{-3}$  contribution. Also, the differences between the two species of tubulin subunit are much less obvious, because of the relative weakness of the third (27 Å) layer line in the X-ray diffraction pattern (no data from other odd-numbered layer lines were included).

We do not know the reason for these remaining differences. Discrepancies in the central sections of the protofilaments could obviously be due to failure of the negative stain to penetrate fully into this region, even in the case of the zinc-tubulin sheets, which seem to stain better than normal tubulin structures. But this explanation is not adequate for the differences observed in the surface structure. One must postulate that the negative stain does not adequately represent the native protein contours. This might be due to selective positive staining<sup>22</sup> of certain parts of the protein molecules. Alternatively, there may be reproducible changes in conformation during negative staining and dehydration of the EM specimens, as there seems to have been a consistent shrinkage of the sheets. Neither of these possible effects could be corrected for when the negatively stained density distribution was 'stretched' (Fig. 4) to adjust the dimensions to those of hydrated protein. Because of this lack of exact correspondence between the two images, we still cannot be sure that the relative phases, especially those related to features on the inside of the cylinder, are quite correct.

Resolution of the remaining uncertainties in the structure at this resolution must await an independent determination of the Bessel function assignments and phases in the X-ray diffraction pattern, for example, by labelling the protein with heavy atoms<sup>23</sup>, if this proves possible. However, the consistency between the results obtained by electron microscopy and X-ray diffraction is clearly much better than it originally seemed to be<sup>5-7</sup> and, for this reason, we believe that the three-dimensional model of zinc-tubulin protofilaments presented here is a good first approximation to the low resolution structure of assembled tubulin.

We thank Drs A. Klug, R. Henderson and P. N. T. Unwin for advice. This work was aided by a grant from the Jane Coffin Childs Memorial Fund for Medical Research. During the course of the work, T.S.B. was a fellow of the Jane Coffin Childs Memorial Fund.

## Polar clearing in the Venus clouds observed from the Pioneer Orbiter

PIONEER Venus 1 was put into a 24-h orbit around the planet on 4 December 1978. Since then, it has made remote sensing observations of the clouds and the overlying atmosphere at IR, visible and UV wavelengths. The IR instrument includes a channel at a wavelength of  $11.5\ \mu\text{m}$ , which is used to measure the effective temperature of the cloud tops. Carbon dioxide, and all of the known constituents of the gaseous atmosphere, are highly transparent at this wavelength. Earth-based telescopic observations at similar wavelengths<sup>1-3</sup> have generally shown fairly uniform temperatures of the order of 240 K across the face of Venus. The accepted interpretation has been that the cloud cover on Venus not only covers the whole planet, but is also extremely uniform. The early Pioneer observations confirmed this general picture, for the equatorial and mid-latitudes which comprise most of the surface area of the planet<sup>4</sup>. Interesting and meteorologically important structure with diurnal, seasonal and random components is found in the Pioneer measurements, as it was in earlier ground-based and spacecraft observations, but this structure has an amplitude of 10 K or less<sup>1-6</sup>. However, these subtle contrasts which dominate thermal maps of lower latitudes change to dramatic structure near the pole. Even the Earth-based observers, who must view the polar regions on Venus at very oblique angles, have reported cold bands surrounding one or other of the poles at various times<sup>2</sup> and occasional polar 'hot spots'<sup>1</sup>. The Pioneer orbit passes almost directly over the pole (inclination =  $105^\circ$ ) and so provides the first good views of this interesting region. The IR instrument was

operated only in its low spatial resolution mode for the first part of the mission. Results from those observations<sup>4</sup> showed a wave-shaped collar of high, cold cloud surrounding the north pole, with warmer cloud temperatures polewards. Close to the pole itself, the observed temperature is the highest anywhere on the planet, not only at the cloud top but also in the overlying atmosphere<sup>4</sup>. We report here the first high data rate, high spatial resolution observations of the polar region. These were obtained on the tenth orbit of Venus on 15 December 1978.

Figure 1 shows a single swath across the planet, covering latitudes from about  $40^\circ$  to  $80^\circ\text{N}$  as shown in Fig. 2. Figure 3 shows an image of the region from a series of contiguous swaths. The individual swaths are obtained as a result of the spinning motion of the spacecraft, which rotates at  $\sim 5$  r.p.m. The separation of the swaths is due to the motion of the spacecraft along its orbit.

These data show an extremely localised, very warm feature at about  $80^\circ\text{N}$  and  $359^\circ\text{E}$  (corresponding to a local time of day of about 9 am). The peak temperature of 260 K is the highest cloud-top temperature ever to be observed on Venus. Because of the abrupt nature of the increase, and also because the Pioneer IR radiometer makes independent measurements of the temperature of the clear atmosphere above the clouds, it is evident that the large temperature contrast is due to a depression or clearing of the cloud layer rather than to an actual temperature increase at a constant height level. This in turn is probably due to strong downwelling in the atmosphere near the pole. To account for the contrast of approximately 45 K between the peak of the anomaly and the nearby cold band which surrounds it, a difference of cloud height of approximately 15 km is required. This follows because the measured temperature lapse rate in the polar region is close to  $3\ \text{K km}^{-1}$  (ref. 5). Cloud height differentials of this magnitude are seldom, if ever, observed on the Earth.

It is interesting to consider how high the temperature would have to rise in an anomaly of this kind in order to correspond to a completely cloud-free atmosphere. To investigate this, we have calculated the transmission profile of a model Venus atmosphere corresponding to the spectral bandpass of the  $11.5\ \mu\text{m}$  channel. As stated previously, this wavelength was selected because it is one of the most transparent in the thermal IR. However, because of the high concentration of  $\text{CO}_2$  on Venus, even this would become opaque (defined as an optical depth greater than unity) by a depth corresponding to a pressure of about 0.8 bar. At this level, the atmospheric temperature is approximately 290 K. Thus, the highest temperature measured approaches, but definitely does not attain, that which would correspond to a totally cloud-free region. However, as can be seen from Fig. 3, the high resolution data sequence ended before the coverage of the feature was completed. The temperature may have risen higher, perhaps even to the temperature corresponding to a total absence of cloud, nearer to the pole itself. An analysis of further high-resolution scans obtained later in the mission will eventually test this hypothesis and also reveal how the feature evolves.

It can be affirmed that the observations presented above constitute new and persuasive evidence for the presence of strong atmospheric subsidence near the poles. This fits very well with the suggestion by Murray *et al.*<sup>7</sup> and Suomi and Limaye<sup>8</sup> of vortex-type circulation at the poles in the UV imaging sequences of Venus by Mariner 10. Suomi and Limaye<sup>8</sup> state that these

**Fig. 1** A single scan across Venus at a wavelength of  $11.5\ \mu\text{m}$  (spectral resolution =  $0.027\ \mu\text{m}$ ) showing the effective cloud-top temperature observed. The scan cuts through the cold polar collar, showing its asymmetry, and through the anomalously hot feature near to, but offset from, the north pole. The scan corresponds to the bottom edge of the image in Fig. 3.

**Fig. 2** Diagram showing the geometry of the observations, and the boundaries of the high-resolution image.

observations of spiral bands of cloud and a poleward component of cloud motion "are compelling suggestions that at least during the 7 days of the Mariner 10 flyby in 1974 the stratospheric circulation was composed of two giant vortices more or less centred on each pole with meridional inflow from low latitudes towards each pole. The vortex . . . would be characterised by a region of mass sink in the polar regions in the upper atmosphere and a mass source at lower latitudes, essentially a hemispheric Hadley circulation cell strongly organised by the vertical zonal flow".

The 'single cell' model for the Venus stratosphere is attractive, not least because it provides an intuitive explanation for the ubiquitous and uniform cloud cover outside the polar domains. It is easy to imagine that the atmosphere may be slowly rising over most of the area of the planet, thus sustaining dynamically the observed cloud deck. This mass flow would then be balanced by relatively rapid descent within the polar vortices. There are difficulties with this, however. First, it is difficult to explain why the 'eye' of the vortex is not centred on the rotational pole. The low resolution data alluded to earlier show clearly that its centre is  $5^{\circ}$ – $10^{\circ}$  from the pole itself. Second, the presence of the thick, high polar collar cloud (segments of which can be seen in Fig. 3) is not explained by a simple vortex circulation and may, in fact, preclude it. Third, the downwelling in the polar region must be explained in terms of a circulation mechanism which produces a poleward meridional flow<sup>8</sup>, but against the gradient of increasing temperature from equator to pole<sup>4</sup>. Such a situation is not

**Fig. 3** An 11.5- $\mu\text{m}$  image of thermal emission from the region near the north pole of Venus delineated in Fig. 2. The data were obtained from the Pioneer orbiter on 15 December 1978. The brightest area is emitting more intensely, and hence is warmer, than its surroundings. The dark (cold) circumpolar collar appears either side of the hot region, and some of its detailed structure can be seen. The limb of the planet is visible at either edge of the frame.

consistent with a classical 'Hadley' type circulation driven by solar heating. The stratospheric dynamics on Venus require some more complex mechanism, perhaps involving motions driven from below.

This is one phase of work carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract NAS 7-100 sponsored by NASA. D.J.D. is supported by a NASA/NRC Resident Research Associateship.

## Evidence for lightning on Venus

WHETHER lightning exists in a planetary atmosphere is a fundamental question for the atmospheric physicist. The conditions within a lightning stroke are far different from those within ambient atmosphere, permitting chemical and physical changes in the atmosphere which are not possible in equilibrium conditions. The relative importance of such nonequilibrium processes depends on the frequency and the location of this electrical activity. Discovery of lightning on other planets would also affect other scientific fields, including studies of planetary magnetospheres and of life. Lightning has been predicted or considered on Venus<sup>1</sup> and Jupiter<sup>2,3</sup>, and evidence for lightning has been obtained with instrumentation on Venera 11 and 12 descent vehicles<sup>4</sup>. Electric fields characteristic of lightning, and acoustic signals, were detected on the dayside of the planet. We

**Fig. 1** The solar zenith angle of the periastron of the Pioneer Venus Orbiter in December 1978 and January 1979 with orbits with impulsive events marked. The events, possibly due to lightning in the atmosphere of Venus, seem to be observed only when the Orbiter is in the shadow of Venus.

present here evidence of lightning on Venus obtained by instruments on the Pioneer Venus Orbiter.

The spacecraft was placed into Venus orbit on 4 December 1978<sup>5</sup>. Results discussed here are derived from observations to 31 January 1979. The periastron of the Orbiter is well within the Venus ionosphere where electromagnetic waves characteristic of lightning might propagate. Initially periastron was in sunlight. However, periastron moved into darkness by the end of December, and at this time the Orbiter electric field detector obtained its first evidence for lightning.

**Fig. 2** A few minutes of electric and magnetic field data observed with Pioneer Venus Orbiter on 21 January, 1979. The measured electric field amplitudes of waves with frequencies *a*, 30 Hz; *b*, 5.4 kHz; *c*, 730 Hz; *d*, 100 Hz. The magnitude of the magnetic field is shown in *e*. Electron density data are shown in *f* (unconnected for densities  $< 500 \text{ cm}^{-3}$ ). Periastron was at 19 h 36 min 32 s.

The electric field detector has sensors which are mounted on the body of the Orbiter spacecraft with an effective antenna length of 0.7 m. The amplitude of the voltage induced on the antenna is measured in four frequency bands centred at 0.100, 0.730, 5.40 and 30.0 kHz, each 30% wide. The amplitudes are telemetered at various rates, commonly a complete spectrum (four measurements) every 0.5 s. The data reported here are from three instruments on Pioneer Venus—the electric field detector<sup>6</sup>, the magnetometer<sup>7</sup>, and the Langmuir probe<sup>8</sup>.

Electric field data from early orbits were carefully inspected for evidence of lightning but none was found. In fact, in the dayside ionosphere, the wave levels were particularly low during these early orbits, especially in the two lower bands. Beginning with periastron data on 30 December 1978, strong, very impulsive signals were often observed at low altitudes. Figure 1 shows the precession of the solar zenith angle of the periastron of the orbit with the days of the low altitude impulsive events indicated. Reception of the waves at the satellite appears possible only when the satellite is in or near the shadow of Venus. In principle, this could be due to a source effect (for example, if venusian thunderstorms occur only at night) or to a propagation effect (for example, if the daytime venusian ionosphere is opaque to the waves). A source effect can probably be ruled out since Venera 11 and 12 lightning observations were made at solar angles  $< 25^\circ$ , and this fact alone suggests that the nightside observations on the Orbiter are associated with changes in the ionosphere.

**Fig. 3** Onboard measurements of the electron density for a typical dayside and nightside ionosphere (dashed line) and for the nightside ionosphere corresponding to the data shown in Fig. 2 (solid line).

Figure 2 shows a fairly typical example from 21 January 1979 when the altitude of periastron was 164 km (at 19 h 36 min 32 s). The impulsive wave events were primarily detected at altitudes less than about 250 km, with regions of low electric field activity in the ionosphere above about 250 km. The magnetic field was about 30 nT during most of the time shown in Fig. 2, giving an electron gyrofrequency of about 840 Hz. Within the density 'dropouts' we use  $N \approx 40 \text{ cm}^{-3}$  as an electron density estimate. For a magnetic field of 30 nT and an electron density of  $40 \text{ cm}^{-3}$ , 100 and 730 Hz waves will propagate in the whistler mode, whereas no cold plasma wave mode will support propagation at 5.4 or 30 kHz. The events are strongest at 100 and 730 Hz although a few events extend to 5.4 kHz as well. The 5.4 kHz data may be due to propagation in other wave modes or may be due to waves leaking out of a nearby region of depleted electron density (common on the nightside of Venus). Figure 3 shows the different character of the ionosphere on the day and night sides of Venus. The dayside is relatively more dense and more regular. The impulsive events occurred at an average rate of about  $0.5 \text{ s}^{-1}$  between 19 h 35 min and 19 h 39 min. The actual

**Fig. 4** The decay of the measured amplitude of an impulsive event on 13 January, 1979. The decay is exponential and apparently due entirely to the electronic averaging in the instrument. This indicates that the length of the input signal was very much less than the time constant of 0.70 s.

rate may have been much higher since the time between measurements was 0.5 s during this period. Venera 11 observed a maximum impulse rate of  $25 \text{ s}^{-1}$  (ref. 1).

Lightning on Earth is very impulsive. A test of the impulsiveness of the events is to observe the decay of the receiver output after an isolated impulse. The pulse shape of such an isolated impulse on 13 January 1979 is shown in Fig. 4. The rise time of the pulse is very short but, as expected, the decay is exponential with a time constant of 0.70 s, consistent with the decay time constant of the receiver.

The following evidence leads to the tentative conclusion that the impulsive events were caused by venusian lightning: (1) The signals are intense and highly impulsive; (2) the signals are detected near periapsis, well inside the ionosphere; (3) the spectral characteristics of the signals are generally consistent with whistler wave propagation up through the ionosphere; (4) the signals are often observed during intervals when low and variable electron densities are measured.

When the nightside densities are as high as  $10^3 \text{ cm}^{-3}$ , the interpretation that the impulsive events were caused by lightning requires that the whistler mode damping that seems to be effective in the dayside ionosphere<sup>6</sup> should be ineffective in the lower density nightside ionosphere. Other interpretations of some of the wave measurements are also conceivable (for example, some observations could represent electrostatic ion acoustic or electrostatic ion cyclotron waves<sup>9,10</sup>, or be due to turbulence near zero frequency<sup>11</sup>). However, many of the impulsive events are detected near regions with local electron densities  $< 10^2 \text{ cm}^{-3}$ , and since the electron energy for Landau damping is proportional to the inverse of the density, the cool electrons near periapsis at night can never provide much damping. Moreover, for densities  $< 10^2 \text{ cm}^{-3}$  and a magnetic field of 30 nT, a 100-Hz whistler mode wave has a wavelength of 10 km or more, and it is almost certain that the spacecraft is frequently as close as the wavelength from the lower edge of the ionosphere. For these cases, and others where ducts might be present, signals from atmospheric lightning should be able to propagate to the spacecraft without any significant damping.

## Observation of magnetic flux ropes in the Venus ionosphere

MAGNETIC field measurements made by the Pioneer Venus Orbiter spacecraft reveal a very low average field strength within the dayside ionosphere of Venus, typically only a few nanoteslas, in contrast to fields of several tens of nanoteslas just outside the ionosphere<sup>1</sup>. Thus, at least in the range of solar zenith angles ( $65-90^\circ$ ) initially probed by the orbiter, the compressed interplanetary magnetic field of the shocked solar wind plasma (the magnetosheath) is effectively shielded from the ionosphere by currents flowing on the ionopause, the boundary between the ionosphere and the magnetosheath. In addition, the magnetic field pressure just outside the ionopause approximately balances the ionospheric thermal plasma pressure<sup>2,3</sup>. However, within this generally low-field region the spacecraft occasionally passes through regions of very large field strength which can sometimes exceed that observed external to the ionosphere. These intense, short-lived enhancements are described here and interpreted to be due to the passage of the spacecraft through 'flux ropes', bundles of twisted magnetic field lines surrounded by ionospheric plasma.

**Fig. 1** Magnetic field enhancements observed within the ionosphere shortly after periapsis (at 1431.56) on orbit 3 of Pioneer Venus. Before and after this interval, the characteristic ionospheric field strength is less than 10 nT, while the peak field just outside the ionopause is  $\sim 55$  nT.

**Fig. 2** *a, b* Comparison of the magnetic structure of one of the enhancements shown in Fig. 1 (*a*), and a model of the enhancement (*b*), the coordinate system is the principal axis system given by minimum variance analysis, and the fields are in nanoTeslas. The model parameters are discussed in the text. 13.5 s of data are shown. Hodograms of the structure (*c*) and the model (*d*). Orbit 3 of Pioneer Venus; 7 December 1978; 1432.37.3–1432.50.8;  $l_A = 3.2$ ;  $l_B = 4.5$ ;  $\rho_{\min} = 2$ .

Figure 1 shows the magnetic field strength observed near periapsis on the third orbit of Pioneer Venus. The spacecraft moves from an altitude of 209 km and a solar zenith angle of  $66.7^\circ$  to an altitude of 332 km and an angle of  $69^\circ$  during this time. Numerous enhancements occur throughout the ionospheric passage, and the field components (not shown) undergo complicated variations within each enhancement. It is unlikely that these variations are purely temporal, as the spacecraft is travelling faster than plausible wave disturbances. For example, with local ionospheric densities  $>10^4 \text{ cm}^{-3}$ , temperatures of roughly 2,000 K (refs 2, 3), and a background field of roughly 2 nT, the Alfvén speed is  $\sim 0.5 \text{ km s}^{-1}$ , while the sound speed is  $\sim 1 \text{ km s}^{-1}$ . The orbital speed of the spacecraft near periapsis is

$\sim 10 \text{ km s}^{-1}$ , so we are probably observing spatial structures. Because the spacecraft grazes these structures at various distances from their centres, the magnitude and duration of the enhancements are variable, as can be seen in Fig. 1. This figure also shows that structures often overlap one another, and for clarity, we have analysed only distinctly separate enhancements.

In an attempt to reduce the field variation to two dimensions, we have performed minimum variance analyses<sup>4</sup> on some of these enhancements. Figure 2*a* shows the field variation, in the principal axis system, of the structure observed between 1432.37.3 and 1432.50.8 UT on orbit 3. The *i*, *j* and *k* components refer to the maximum, intermediate and minimum variance directions respectively. Figure 2*b* shows the results of a minimum variance analysis applied to a passage through a model field describable by the following equations:

$$B_\phi = B(\rho) \times \cos(\alpha(\rho)),$$

$$B_z = B(\rho) \times \sin(\alpha(\rho))$$

where

$$B(\rho) = B_0 \times \exp(-\rho^2/l_B^2)$$

and

$$\alpha(\rho) = \pi/2 \times (1 - \exp(-\rho^2/l_A^2))$$

These equations define a helical magnetic field, whose magnitude and pitch  $\alpha$ , depend on the radial distance,  $\rho$ , from the axis of the structure.  $B_\phi$  and  $B_z$  are, respectively, the azimuthal and axial components of the field. The scale lengths  $l_A$  and  $l_B$  determine how rapidly the pitch and magnitude vary with distance from the axis. For the case shown in Fig. 2*a, b*  $l_A = 3.2$ ,  $l_B = 4.5$ , and the distance of closest approach to the axis was 2.0. Hodograms of both the observations and the model are shown in Fig. 2*c, d*; the field vector swings through a full  $180^\circ$  in the *i-j* plane, passing through maximum magnitude near  $90^\circ$ . The distinctive variation in  $B_k$  is a result of passing through the helical structure off-axis.

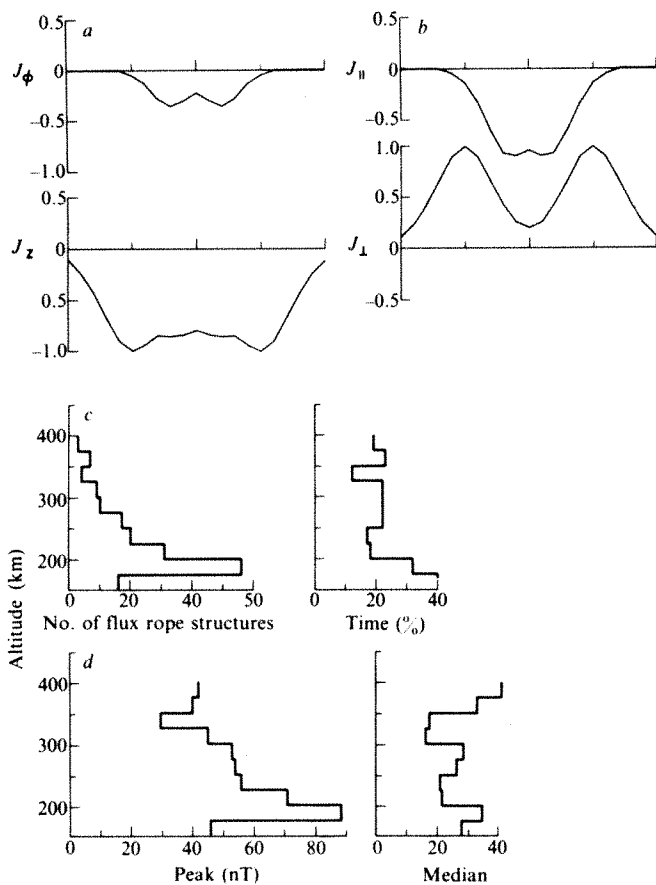

The magnetic configuration suggested by the data and described explicitly by the model is shown in Fig. 3. Because of the helical nature of the magnetic field, the structure resembles a rope of twisted magnetic flux tubes: the magnetic field is axial and at its peak strength in the centre of the structure, becoming weaker and more azimuthal with increasing distance from the axis.

The currents which produce this helical magnetic structure are shown in Fig. 4*a, b*, both in the cylindrical coordinates of the structure and in coordinates parallel and transverse to the magnetic field at each point. Note that throughout the modelled passage the axial current is always dominant.

To determine the source and evolution of these flux ropes, we next examine their amplitude and occurrence frequency with altitude. Figure 4*c, d* shows these quantities combined for orbits 3, 4, 6 and 7. The altitude range is divided into 25-km bins, and the total number of flux rope structures per bin is shown in Fig. 4*c*. Because of its orbit, the spacecraft spends more time in the low-altitude bins than in the high, and this effect can be seen as an increase in total number of structures per bin with decreasing altitude. The altitude interval 150–175 km was sampled only during orbit 7, and does not have an observing time comparable to the higher altitude bins. To correct for the varying observing time with altitude we have determined the ratio of the total time spent within flux ropes to the total time spent within an altitude bin, as shown in Fig. 4*c*. There seems to be a slight increase in

**Fig. 3** Inferred magnetic structure of an ionospheric flux rope. The field is weak and azimuthal in the outer regions, becoming much stronger and more axial near the centre of the structure.

**Fig. 4** *a, b* Current densities (arbitrary units) of the model structure in Fig. 2*a, b*. The cylindrical components (*a*)  $J_\phi$  and  $J_z$  refer to the azimuthal and axial current contributions, while  $J_\parallel$  and  $J_\perp$  (*b*) are the contributions parallel and transverse, respectively, to the local magnetic field vector. The abscissa is distance along the spacecraft trajectory which in this case does not pass through the centre of the rope. Distributions of occurrence frequency (*c*) and amplitude (*d*) with altitude.

occurrence rate at lower altitudes. Additional data, especially when Pioneer Venus returns to the dayside ionosphere, will be needed to confirm this tendency.

If the magnetic field in these structures is in pressure balance with the surrounding ionospheric plasma, one would expect their characteristic field strength to increase with decreasing altitude, as the plasma thermal pressure increases. Figure 4*d* shows the peak flux rope amplitude observed within each altitude bin, and indeed, the amplitude seems to increase with decreasing altitude. The 150–175 km bin is the most notable exception to the trend, perhaps because this lowest altitude interval was sampled only on orbit 7. The right portion of Fig. 4*d* shows the median of the distribution of flux rope amplitudes within each bin. The distribution suggests that, at altitudes below 350 km, amplitudes increase overall with decreasing height, but results above 325 km have less statistical accuracy because of the small number of samples in those intervals.

Although the results shown are only based on four orbits of data they, nevertheless, carry implications for the source and evolution of flux ropes. First, the suggestion that these structures are more numerous at lower altitudes may be due to either a 'piling up' effect or to a source at low altitudes. The former might occur if magnetosheath magnetic flux tubes were pulled into the ionosphere by solar wind convection, such as has been proposed for the terrestrial magnetopause<sup>5</sup>. These structures would slow down and pile up in the denser, slower moving lower ionosphere. If, however, these structures result from a source in the

lower ionosphere, they might percolate upwards due to buoyancy; indeed, the enhanced magnetic field pressure within these structures implies the reduction of the plasma thermal pressure there, and if this shows up as a reduction in ion/electron number density, flux ropes must be buoyant with respect to the surrounding plasma. A similar process is believed to occur in the terrestrial equatorial ionosphere<sup>6</sup>. The helical nature of flux ropes could develop from velocity shear in the ionosphere, due perhaps to a viscous interaction with the magnetosheath at the ionopause. Given the observed ionospheric temperatures and densities, and flux rope scale diameters between 10 and 100 km, the magnetic diffusion time of such structures would be many hours. Thus flux ropes are likely to persist long enough to be transported, not only from the ionopause to the lowest ionospheric levels (or vice versa), but from the subsolar region to the terminator as well.

Whatever their source, these ionospheric flux ropes may play an important part in the solar wind–ionosphere interaction, and ionospheric plasma transport and heating. Analysis of the early Pioneer Venus data is continuing to define better the nature of this unexpected phenomenon.

## Polar heating and the shape of Venus

ON Venus, as on the other terrestrial planets, temperature variations are expected between equator and poles and between day and night. Several attempts have been made to measure these deviations from circular symmetry in the radio emission from Venus using interferometric techniques, for example, Berge and Greisen<sup>1</sup> at a wavelength of 3.1 cm and Sinclair *et al.*<sup>2–4</sup> at 11 cm. The observed variations are found to be very small. Berge and Greisen<sup>1</sup> report a slight increase in the brightness temperature towards the poles, but the effect was less than one standard deviation of the measurements. A larger increase in brightness temperature towards the poles was seen by Sinclair *et al.*<sup>4</sup>. We report here a similar polar brightening at a wavelength of 6 cm which persuades us that the effect is real. This brightening is a surface or near surface phenomenon as at 6 cm about half the flux is from the surface and half from the lower atmosphere.

Our observations were made with a two-element interferometer at Owens Valley Radio Observatory between 6 May and 13 May 1977, near inferior conjunction with Venus. Each element of the interferometer is a steerable, parabolic, 27-m diameter antenna with a linearly polarised feed that can be rotated by remote control. The polarisation of the E-vector accepted from Venus was either perpendicular or parallel to the baseline projected on the planet and was alternated between successive records. The observational records were 5 min long with calibration records every 45–60 min. Small-diameter extragalactic radio sources with accurately known positions were used to calibrate the fringe amplitude and phase.

An east–west (E–W) baseline of 396 m and a north–south (N–S) baseline of 456 m were selected to observe near the first

null of the planet's 6-cm visibility function, which is the Fourier transform of the spatial brightness temperature distribution. These baselines were nearly parallel to N-S and E-W directions on Venus, as well as on the Earth. The resulting visibility functions are most conveniently expressed as a function of  $\beta$ , the instantaneous projected baseline length in wavelength times the angular radius of the planet based on a physical radius of 6,100 km. The value of  $\beta$  at the first null of the visibility function,  $\beta_0$ , varies inversely with the width of the brightness-temperature distribution along the baseline. Thus, by comparing the E-W and N-S values of  $\beta_0$ , the directions in which the planet is wider and/or hotter towards the limbs can be determined. We cannot uniquely deconvolve variations in the planet's radius and temperature variations. Our observations were all near the first null and determine  $\beta_0$  quite accurately.

An interferometer measures both the amplitude of the visibility function and the phase. Theoretically, phase data can be used to detect asymmetries about a line through the centre of the disk perpendicular to the baseline. However, our phase data from the N-S baselines were affected by antenna pointing errors caused by strong winds, and we could not determine the amount of asymmetry between the north and south poles on Venus. To a close approximation, such pointing errors do not affect the measurements of  $\beta_0$ . Sinclair *et al.*<sup>4</sup> report that the pole-to-pole asymmetry is <3 K at a wavelength of 11 cm. Consequently, we have assumed that equator-pole variation is symmetric, that is, that the brightening occurs equally at both poles. Observations on our E-W baseline were not affected by pointing errors as the winds at this time were low.

Figure 1 shows our measurements with polarisation perpendicular to the baseline for the E-W and N-S baselines. To find the best fit value for  $\beta_0$ , we used least squares to fit the quadratic formula,  $B(\beta - \beta_0) + C(\beta - \beta_0)^2$ , to the data for a series of values of  $\beta_0$ . Because a quadratic is a good approximation of the true visibility function over only a limited range of  $\beta$ , we consider only data points with  $0.56 < \beta < 0.68$  for the perpendicular polarisation. We determine the value of  $\beta_0$  that minimises the sum of the squares of residuals:

$$S = \sum_i (f_i - [B(\beta_i - \beta_0) + C(\beta_i - \beta_0)^2])^2$$

where  $f_i$  = data point at  $\beta_i$  and  $B$  and  $C$  are the best fitting coefficients for each value of  $\beta_0$ . The best fitting values for  $\beta_0$  are  $0.6207 \pm 0.0005$  for N-S<sub>⊥</sub> and  $0.6214 \pm 0.0004$  for E-W<sub>⊥</sub>, where the errors are standard deviations determined from the

**Fig. 1** Visibility data for *a* N-S and *b* E-W baselines with polarisation perpendicular to the baseline. *a*,  $\beta_0 = 0.6207 \pm 0.0005$ ; *b*,  $\beta_0 = 0.6214 \pm 0.0004$ . The visibility is plotted plus or minus according to the phase. The curves shown and the values given for  $\beta_0$  were determined by a least-squares fit of a quadratic as described in the text. The radius used in calculating  $\beta$  was 6,100 km.

data. The difference in nulls  $\Delta\beta_0$ , is  $0.0007 \pm 0.0006$ , where the error again is the standard deviation.

Our measurements with polarisation parallel to the baseline are shown in Fig. 2. The best fit values over the range  $0.55 < \beta < 0.67$  for  $\beta_0$  are  $0.6075 \pm 0.0005$  for N-S<sub>||</sub> and  $0.6082 \pm 0.0004$  for E-W<sub>||</sub>. The parallel nulls are at smaller values of  $\beta_0$  than the perpendicular nulls because of a maximum in the brightness in this polarisation at the Brewster angle. The difference in nulls for the parallel polarisation is also  $0.0007 \pm 0.0006$ .

As the measurements in the two polarisations are statistically independent, we may combine our results to get  $\Delta\beta_0 = 0.0007 \pm 0.0004$ . Note that in both polarisations the N-S  $\beta_0$  is less than the E-W  $\beta_0$ . This difference implies that the planet is either larger or brighter at the limb along the N-S direction than along the E-W direction. This result is surprising. If we assume that the  $\Delta\beta_0$  is produced by a variation in radius of a uniformly bright planet, the planet's figure must be  $7 \text{ km} \pm 4 \text{ km}$  prolate. If the planet's gravitational equipotentials are prolate to this extent as well, the resulting  $J_2$  is about  $-10^{-3}$ , but  $J_2$  for Venus has been estimated to be  $-2 \pm 5 \times 10^{-6}$  by Esposito (personal communication) and  $4.0 \pm 1.5 \times 10^{-6}$  by Akim *et al.*<sup>5</sup>

It is difficult to compare our results with the polar heating reported by Sinclair *et al.*<sup>4</sup>, because they do not report a model-independent measure of the effect such as the prolateness of an equivalent, uniformly bright elliptical disk. Sinclair *et al.* altered their standard circularly symmetric Venus model to include a latitudinal surface temperature variation of the form  $\Delta T \sin^2 \varphi$  where  $\varphi$  is the latitude. The form  $\sin^2 \varphi$  was chosen as it is the first even term of a harmonic expansion. The resulting surface temperature at each latitude was adiabatically extrapolated upwards through the atmosphere. Visibility functions computed from this model were compared with their measured visibilities and  $\Delta T = 16 \pm 2.5 \text{ K}$  was estimated. Apparently, the quoted error does not include any model uncertainties. A similar procedure with our data would yield a  $\Delta T$  of about 5 K. The magnitude of the effect may be variable.

There are several viable phenomena that would cause the poles of Venus to be hot or to appear hot at radio wavelengths, although the thermal time constant in the lower venusian atmosphere is very long and, on theoretical grounds, one expects nearly constant temperatures on any equipotential surface. The absence of appreciable E-W asymmetries in the radio brightness across the terminator<sup>4</sup> strongly supports this idea. However, the global atmospheric circulation may cause relative heating towards the poles. There may be strong downwelling causing warming associated with the circumpolar vortex<sup>6</sup>. IR measurements on the Pioneer Venus Spaceprobe<sup>7</sup> detected a brightening of  $\sim 10 \text{ K}$  over the north pole, down to an altitude level of about 70 km. These measurements are only sensitive to the atmospheric temperatures above the clouds. This region contributes nearly zero flux at radio wavelengths. It is unlikely that these elevated temperatures above 70 km are related to the brightening at the surface. A second possible cause of polar heating is a slight topographical flattening relative to the gravitational equipotentials possibly due to a more rapid spin state in the past or to the dynamic alignment of the planet's rotation axis and its axis of greatest moment of inertia. The latter case would apparently also require a more rapid rotation in the past. It is also possible that topography generated by geological processes could coincidentally cause this effect. Two phenomena that would increase the radio brightness towards the poles without increasing the physical temperature are a systematic decrease in radio opacity caused by a thinning of the clouds towards the poles or a systematic increase in surface emissivity away from the equator due to latitudinal differentiation of the surface geology.

The possibility of a greater topographic than gravitational oblateness is explored below. Atmospheric circulation will be considered elsewhere. It is not unreasonable to expect Venus's figure to have a small excess topographic oblateness. The Earth's figure has an excess oblateness of about 0.5 km, primarily because a majority of the continents are located nearer

**Fig. 2** Visibility data for *a* N-S and *b* E-W baselines with polarisation parallel to the baseline. *a*,  $\beta_0 = 0.6075 \pm 0.0005$ ; *b*,  $0.6082 \pm 0.0004$ . Otherwise as Fig. 1.

the Equator than the poles<sup>8</sup>. The Moon and Mars also have excess oblateness of about the same magnitude<sup>9,10</sup>.

Model calculations were carried out to determine how large a bulge is required to explain our observations. In the model, the figure of the planet is assumed to be an oblate spheroid. In general, the gravitational equipotentials are oblate also due to the oblate figure and rotation. However, if the planet is not in hydrostatic equilibrium, the topographical oblateness will exceed the gravitational oblateness unless the density distribution is prolate. For simplicity in calculations, the gravitational equipotentials in the model are assumed to be spheres. The atmosphere is well mixed so the surfaces of constant temperature and pressure are also spherical. The poles are lower in the atmosphere than the equator and are, therefore, warmer. An atmospheric model and a computational method similar to that of Muhleman *et al.*<sup>11</sup> are used to calculate brightness temperatures which are integrated numerically over the planet's disk to find the model visibility function for an E-W and a N-S baseline. In calculating brightness temperatures, the effects of absorption, emission and refraction in the atmosphere are considered along with the effects of reflection and emission by a dielectric surface. We find that a topographical oblateness of  $0.6 \text{ km} \pm 0.4 \text{ km}$  will yield a  $\Delta\beta_0$  that agrees with our observations. We believe that this is a good approximation of the amount by which the topographical oblateness must exceed the gravitational oblateness. This amount of oblateness together with the  $7.8^\circ \text{ km}^{-1}$  lapse rate leads to the poles being  $5^\circ \pm 3^\circ$  warmer than the equator.

To determine whether the excess topographical oblateness could be due to a fossil rotational bulge, we use the model of Melosh<sup>12</sup> for a despun planet. The structure of the planet in this model is an elastic shell over a fluid interior. We assumed an initial rotation period of 1 day and a density contrast between the interior and the elastic shell of 1.5–2.0. We find that when the excess topographical oblateness is  $0.6 \pm 0.4 \text{ km}$ , the gravitational field generated has a  $J_2$  an order of magnitude above the observational limit. These results indicate that the presence of a fossil rotational bulge on Venus large enough to explain our observations is unlikely. However, the polar heating could still be due to regional isostatically compensated changes in the topography which would have less impact on  $J_2$ .

In conclusion, our observations are consistent with previous work that has shown that the disk of Venus is nearly circularly symmetric at radio wavelengths. However, a small amount of polar brightening is present. We cannot yet determine the cause of this phenomenon although we have argued against the possibility of a fossil rotational bulge large enough to explain the result. As the poles of Venus have other interesting aspects involving atmospheric temperatures and circulation, they are an area worthy of future investigation.

## X-ray, optical and radio observations of A1710–34

SAS 3 ROTATING modulation collimator (RMC) measurements are reported here which yield a new, more precise, position for the Ariel 5 X-ray source A1710–34 (ref. 1). We also report optical observations of stars in the X-ray error box and discuss evidence obtained with the Parkes 64 m radio telescope for 2-cm radio emission from the vicinity of the X-ray source.

Measurements were made of A1710–34 with the 2.3' and 4.5' FWHM RMC detectors on the SAS 3 X-ray observatory<sup>2,3</sup>. These detectors are sensitive in the range 2–11 keV. Two independent sets of position measurements were made between 1600 UT 16 July and 1200 UT 22 July 1978. Details of the observations and the most probable position for the source (which we designate 2S1711–339) are given in Table 1. This position is 2.2 arc min from the most probable position determined using the Ariel 5 satellite and is therefore just inside the Ariel 5 error box. The 90% error circle of the new position has a radius of 40 arc s. A finding chart from the SRC Schmidt Survey J-plate is presented in Fig. 1.

The error circle for this observation of 2S1711–339 includes seven stars of the European Southern Observatory (ESO) quick blue survey plate with magnitude,  $m_{\text{pg}} \leq 20$ . The brightest star (number 1, Fig. 1) has a magnitude,  $m_{\text{pg}} \sim 15$ . The Anglo-Australian Telescope and the RGO spectrograph (140 Å mm<sup>-1</sup> dispersion) were used to obtain a spectrum (3,200–7,000 Å) of this star. The star is of spectral type G0 and has no perceived emission lines. We therefore have no spectroscopic evidence to suggest that it is the optical counterpart to the X-ray source.

The SRC-J survey plate shows that the X-ray error circle lies in the direction of a dust lane. Absorption is particularly strong in the eastern half of the error circle. If the X-ray low energy spectrum is heavily cut off, the optical candidate is more likely to be faint and to the east behind the dust lane. Low-energy X-ray observations would be useful to clarify this particular point. No particularly blue or red stars or variables could be identified by comparing ESO (blue) and SRC (yellow) survey plates.

**Table 1** RMC observations of A1710-34 (2S1711-339)

Date (1978)	Exposure	Collimator	RA (1950)	Dec (1950)	Intensity $\mu\text{Jy}$ (2-11 keV)
0700 UT 20 July	49,500 s	2.3' FWHM	257.7579	-33.9897	$13.2 \pm 2.2$ (6 $\sigma$ )
1200 UT 22 July			17 h 11 min 1.9 s	-33°59'23"	
0700 UT 20 July	49,500 s	4.5' FWHM	257.7500	-33.9978	$14.6 \pm 2.3$ (7 $\sigma$ )
1200 UT 22 July			17 h 11 min 0.0 s	-33°59'52"	
1600 UT 16 July	74,000 s	2.3' FWHM	257.7583	-33.9908	$16.6 \pm 2.6$ (7 $\sigma$ )
0500 UT 20 July			17 h 11 min 2.0 s	-33°59'27"	
1600 UT 16 July	74,000 s	4.5' FWHM	257.7554	-33.9908	$15.3 \pm 2.2$ (7 $\sigma$ )
0500 UT 20 July			17 h 11 min 1.3 s	-33°59'27"	
Average			257.7554	-33.9922	$14.9 \pm 1.2$
			17 h 11 min 1.3 s	-33°59'32"	

**Table 2** Summary of X-ray, radio and optical observations of A1710-34

Waveband	Position (1950.0)		Error circle radius (90% confidence)	Intensity
	RA	Dec		
X-ray (2-11 keV)	17 h 11 min 1.3 s	-33°59'32"	40 arc s	$14.9 \pm 1.2 \mu\text{Jy}$
Radio (2 cm)	17 10 52	-34 00 36	2.2 arc min	$23 \pm 5 \text{ mJy (max)}$
Optical (star 1)	17 11 1.32	-33 59 12.8	2 arc s	$m_{\text{pg}} \sim 15$

The region of the sky in the vicinity of A1710-34 (2S1711-339) has been searched for 2-cm radio emission using the Parkes 64m radio telescope with a full width to half-power beam of 2.2 arc min. Dual-beam switching between two identical beams separated by 6.5 arc min was used. The measurements were made in June 1977, August 1977 and April 1978 during a comprehensive search<sup>4</sup> for new radio counterparts of X-ray sources using Ariel 5, SAS 3 RMC and HEAO 1 positions. The new X-ray position was not known at the time of these observations.

No significant signal was detected from the vicinity of A1710-34 (2S1711-339) in June 1977 or April 1978. Two-sigma upper limits were 66 and 12 mJy respectively. A flux density of  $23 \pm 5 \text{ mJy}$  was detected in August 1977. As the

source was too weak for a reliable radio position determination, the beam was pointed at the Ariel 5 RMC source position. The sensitivity to a point source at the centre of the SAS 3 X-ray error circle would be  $\sim 13\%$  of the on-axis response.

Radio counterparts of galactic stellar X-ray sources tend to be very variable. Thus, for example, the radio emission from Sco X-1 varies in an irregular manner with a typical time scale of hours. The range of variability is about two orders of magnitude<sup>5</sup>. GX9+1 and GX17+2 exhibit short term variability of the Sco X-1 type<sup>6</sup>. Circ X-1 is also variable on a time scale of hours<sup>7</sup>.

We have applied the  $\chi^2$  test to the hypothesis that the radio signal seen in August 1977 could have occurred by chance from a source of constant flux density equal to the weighted mean of the three observations. This gives  $\chi^2 = 7.7$  for 2 d.f. The probability of obtaining a value of  $\chi^2 \geq 7.7$  is about 2%. It therefore seems reasonable to assume that A1710-34 (2S1711-339) is a variable radio emitter with an intensity which rises above the threshold of the Parkes radio telescope at 2 cm only during periods of major flaring.

We conclude that there is probably a variable 2-cm radio source in the vicinity of A1710-34 (2S1711-339) but that further observations are required to determine the position accurately. In Table 2 we summarise the observations made in the three different wavelength bands.

## On the detection of jovian companions to white dwarfs

BRACEWELL<sup>1</sup> has recently proposed detection of planetary companions to nearby stars by means of a spinning IR interferometer. In particular, he notes that at far IR wavelengths, the emissivity ratio of the planet to the star increases by five orders of magnitude over equivalent values in the visible. I point out here that more than another three orders of magnitude in sensitivity is gained by choosing white dwarfs as the observational objects, which may permit detection of jovian or black dwarf companions by direct photometry from a space telescope with photon-limited, far IR detectors.

Compared with the Sun, a typical DA white dwarf has a surface area only  $1\text{--}2 \times 10^{-4}$  as great, while its photospheric temperature is approximately double. Thus, at wavelengths in the Rayleigh–Jeans regime, an observer would detect 2,500–5,000 times fewer photons from a white dwarf than from a solar-type star at the same distance. The key assumptions to this proposal then are that planets of comparable or greater than jovian mass will (1) survive the parent star's red giant phase, and (2) presently contain internal energy sources similar to that of Jupiter. I discuss each of these assumptions in turn.

The most serious threat to a planet's survival is engulfment by the red giant photosphere. Viscous drag on the planet's orbital motion would then lead to a spiralling into the stellar core. The maximum luminosity<sup>2</sup> of a red giant with a  $1.4 M_{\odot}$  carbon-oxygen core (that is the Chandrasekhar limit) is  $\sim 5.2 \times 10^4 L_{\odot}$ . If the red giant's effective temperature is  $\geq 2,500$  K, all planets with orbital semi-major axes  $> 5.7$  AU should remain outside the photosphere. For a  $1.0 M_{\odot}$  core, the equivalent value is 4.2 AU. Runaway atmospheric evaporation might also cause planetary destruction. However, Jupiter's atmosphere must be heated to temperatures far above 3,000 K ( $GM_p/kR_p \sim 180,000$  K) before significant quantities of atomic hydrogen will escape. Therefore, as long as a jovian planet remains outside the red giant photosphere, it will probably survive and perhaps even grow slightly from stellar wind accretion.

Both Jupiter and Saturn have internal energy sources. For Jupiter, this source provides more than half its observed thermal emission. Though gravitational contraction may be partially responsible, most astronomers favour an explanation relying on the radiation of primordial heat of formation. Graboske *et al.*<sup>3</sup> have calculated the initial contraction and subsequent evolution of a  $0.0095 M_{\odot}$  protoplanet and found that after a relatively short time ( $O(10^6 \text{ yr})$ ) spent along the Hayashi track, a rapid transition to the cooling curve of a very cold degenerate dwarf occurs. In this latter regime,  $\log L/L_{\odot}$  scales as  $-1.3 \log t$ . As the average age of a white dwarf (including its progenitor's lifetime) is somewhat greater than half that of the Galaxy, the present

luminosity of a hypothetical jovian companion should remain at approximately half its value at  $t = 4.6 \times 10^9 \text{ yr}$ , the age of our Solar System. Thus, one expects relatively strong internal emission to be a general property of all planets of jovian mass or greater.

The three or more orders of magnitude gained in relative sensitivity by the choice of white dwarfs rather than solar-type stars suggest that planetary companions might be detected as an 'IR excess' if advanced detectors become available. Adopting sample parameters of  $\lambda = 40 \mu\text{m}$ ,  $\Delta\lambda = 10 \mu\text{m}$ ,  $R_{\text{WD}} = 0.013 R_{\odot}$ ,  $R_p = 0.1 R_{\odot}$ ,  $T_{\text{WD}} = 10^4 \text{ K}$ ,  $T_p = 120 \text{ K}$ , and a distance of 10 pc, a collecting area of  $10^4 \text{ cm}^2$  would receive  $\sim 180$  photons  $\text{s}^{-1}$  from the white dwarf and  $\sim 20$  photons  $\text{s}^{-1}$  from the planet. A hypothetical photon-limited detector above the Earth's atmosphere could reveal the excess planetary signal with a signal-to-noise ratio  $> 10$  in less than a minute. Confusion with the relic circumstellar dust shell of the red giant is unlikely because it should have been quickly swept away by the ram pressure associated with the white dwarf's motion through the interstellar medium. Zodiacal dust, however, may lead to serious background noise limitations<sup>1</sup> and increase detection times for a diffraction limited telescope by as much as a factor of 1,000 at low ecliptic latitudes.

One might also detect or set upper limits on the number of substellar, degenerate 'black dwarfs'<sup>4</sup> in the mass range  $10^{-3}$  to  $\sim 0.06 M_{\odot}$  associated with white dwarfs. Such objects may provide an important contribution to the mass density, both locally and in clusters of galaxies<sup>5,6</sup>. Their IR luminosity should scale at least linearly with mass. The advantage of a search in the immediate vicinity of a white dwarf is simply that one has a quite definite, highly localised position on the sky to measure. For a background-limited detection system, this allows one to maximise the signal-to-noise ratio until either the diffraction limit or the effective 'seeing' limit is reached.

There are over a dozen single white dwarfs known within 10 pc of the Sun<sup>7</sup>. A far IR survey of these stars from a space-borne telescope might quickly reveal whether solar system formation was a common event. A positive answer would give great impetus towards the construction of a more elaborate planet-detector, such as that proposed by Bracewell.

## Do comets provide material for the anomalous component of the cosmic rays?

MATTER from comets is proposed here to form a significant part of the source material for the 'anomalous component' of the cosmic rays. As a result it is concluded that certain molecular ions, such as  $\text{CO}^+$ , should be present at energies around 10 MeV per nucleon.

The spectra of the nucleonic component of cosmic radiation in the energy band 1–60 MeV per nucleon have produced a number of surprises. The most dramatic of these concerned the fluxes of oxygen and carbon. Jokipii<sup>1</sup> gave minimum flux values in the region 5 MeV per nucleon for hydrogen and helium which essentially divided the solar particles on the low energy side from the true cosmic radiation at the higher energies. The

Chicago group reported in 1973<sup>2</sup> that the shape of the helium spectrum had changed in that the minimum reported earlier had now been filled in, whereas the hydrogen spectrum was essentially unchanged. Hovestadt *et al.*<sup>3</sup> also detected in 1973 an anomalous flux of oxygen centred around 5 MeV per nucleon; as there was no corresponding flux of carbon the C/O ratio had changed by a considerable factor. Later experiments confirmed these measurements and showed the oxygen flux to be 20 times the value of the carbon flux at this peak. This is in complete contrast to the situation below 1 MeV per nucleon or above 60 MeV per nucleon where the C/O ratio remained close to unity. The later measurements also showed a substantial enhancement of nitrogen, and indicated a likely enhancement of neon. The total flux of the heavier elements is  $\sim 1.0 \text{ m}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$ , in the band  $3 < E < 60 \text{ MeV}$  per nucleon and that of helium is a few times larger.

The discovery of the anomalous component was very surprising and demanded an explanation. The generally accepted explanation is due to Fisk, Kozlovsky and Ramaty<sup>4</sup> who postulate that these particles carry only a single charge in contrast to both the solar corpuscular radiation at  $\sim 1 \text{ MeV}$  per nucleon and the cosmic rays at higher energies which are fully stripped. The consequently high magnetic rigidity ( $\sim 2 \text{ GV}$ ) is an essential feature of their explanation. They envisage the following stages: (1) The passage of the Solar System through the local interstellar gas sweeps aside charged ions, while the neutral atoms are able to penetrate the magnetic cavity of the Sun. A fraction of these atoms is ionised well within the solar cavity. Species likely to be uncharged in interstellar space include He, N, O, Ne since their first ionisation potential is higher than that of the interstellar hydrogen which shields them. (2) After ionisation the singly charged species are carried by magnetic disturbances out to  $\sim 50 \text{ AU}$  where magnetic inhomogeneities accelerate them preferentially, owing to their high rigidity. They retain their unit charge; the mean lifetime for further ionisation will be in the range  $10^6$ – $10^8 \text{ s}$ , depending principally on their distance from the Sun. (3) After acceleration the ions, still presumably singly charged, diffuse through the Solar System, losing little energy from adiabatic deceleration. Again this is due to their rigidity being so much higher than cosmic ray and solar species of comparable energy that are fully stripped.

This model accounts for the particular enhancement of He, N, O and Ne atoms in terms of the magnitude of their first ionisation potential. The ions are introduced to the acceleration mechanism by being ionised well within the solar cavity. The onset of the anomalous component in 1973 and its continuation to the present is presumed to be concerned with the solar cycle and its effect on the acceleration mechanism.

If stages (2) and (3) operate on singly charged ions, clearly any other source of such ions might well contribute to the anomalous component. Comets seem to be such a source. The coma consists of neutral atoms and molecules which are the sublimation products from the cometary nucleus. The most abundant species in the coma seem to be degradation products of  $\text{H}_2\text{O}$ . In addition, in most comets, ionised atoms and molecules are swept by the solar wind into the familiar cometary tail. In this ion tail the spectrum from  $\text{CO}^+$  is usually the most prominent component. Ions liberated by comets could be a direct source of material for stages (2) and (3) above. Further, atoms and molecules from the coma might be an alternative source of neutral particles for stages (1) to (3) above. The presence of molecules in this cometary debris leads us to an interesting possibility. These molecules might also be present in the anomalous component, as in many cases their lifetimes for further ionisation or dissociation have values comparable to those of atomic ions. A cometary source of material would have the following features.

First, the total amount of  $\text{H}_2\text{O}$  shed by short period comets is estimated by Delsemme<sup>5</sup> to be  $\sim 5 \times 10^7 \text{ g s}^{-1}$ . In addition the amount of more refractory material released by comets to form meteoroids that produce the zodiacal light and the Gegenschein is estimated by Whipple and Huebner<sup>6</sup> as  $1$ – $3 \times 10^7 \text{ g s}^{-1}$ . These values are comparable with that coming in from the interstellar

**Table 1** Binding energies of some abundant molecules and molecular ions

	Dissociation energy (eV)	Ionisation energy (eV)		Dissociation energy (eV)	Ionisation energy (eV)
$\text{H}_2$	4.54	15.43	$\text{H}_2^+$	2.71	16.3
CH	3.52	11.13	$\text{CH}^+$	3.65	17.2
$\text{C}_2$	6.27	12.0	$\text{C}_2^+$	5.53	16.8
CN	8.01	14.3	$\text{CN}^+$	4.96	19.5
CO	11.20	14.01	$\text{CO}^+$	8.45	22.1
NH	3.27	13.10	$\text{NH}^+$	3.77	18.3
$\text{N}_2$	9.88	15.58	$\text{N}_2^+$	8.83	23.4
NO	6.57	9.25	$\text{NO}^+$	10.93	25.6
OH	4.45	13.17	$\text{OH}^+$	4.88	18.5
$\text{H}_2\text{O}$	5.17	12.6	$\text{H}_2\text{O}^+$	5.75	19.3
$\text{CO}_2$	5.51	13.77	$\text{CO}_2^+$	5.35	19.0

medium as neutral atoms, which for oxygen is estimated as  $\sim 5 \times 10^7 \text{ g s}^{-1}$ , by Fisk *et al.*<sup>4</sup>

Second, when first ionised the atom or molecule has a velocity and a component of momentum transverse to the magnetic field almost identical with the values possessed by the interstellar atoms.

Third, the position of the maximum release of cometary material is in the region of 1 AU, bracketed by the mean distances reached by neutral He, N and O before ionisation ( $0.5$ – $4 \text{ AU}$ )<sup>7</sup>.

Finally, the chemical composition of comets has several features in common with that of the anomalous particles. The detected spectra suggest that the principal components are degradation products of  $\text{H}_2\text{O}$ . However, contributions from the refractory material could include a greater variety of elements, for example, Mg and Si.

These points indicate that cometary material is apparently a good candidate for the source of at least some part of the anomalous component. The O/C ratio may place a constraint on the proportion of the anomalous component from comets, but cometary abundance values could well encompass the 20:1 ratio that one has from experiments on the anomalous component. One would not, however, expect a significant helium or neon contribution from a cometary source. The helium flux is well established, and has an abundance a few times that of oxygen, but the data for neon are dubious and are based on a very small number of detected particles, and could have been produced by incident molecular ions, such as CO, rather than neon. The presence therefore of inert gases in significant amounts implies that cometary material cannot be the only source of the anomalous component.

Finally, we would like to consider in further detail the possibility of molecular ions being present in the anomalous component. Table 1 lists some properties of appropriate molecules and molecular ions. Note that the stability of molecular ions against dissociation is comparable with their parent molecules, and their ionisation energy averages 1.5 times that of their parents. In practice the longevity of a molecular species in space is determined principally by whether any copiously produced excited states have a reasonably high dissociation probability. In  $\text{O}_2$ , for example, UV absorption in the Schumann–Runge bands produces dissociation, which is a mechanism of considerable consequence, being the first stage of ozone production in the atmosphere. In contrast there are no such  $\text{N}_2$  states abundantly produced and the effective threshold for  $\text{N}_2$  is ionisation. The longevity of certain molecules, when essentially at rest at about 1 AU, has been estimated by Siscoe and Mukherjee<sup>8</sup> and the figures computed are in the range  $10^6 \text{ s}$ .

As any molecular ion has one fewer weakly bound electron than its parent, and since its ionisation energy is  $\sim 1.5$  times higher, its ionisation cross-section will be significantly smaller than that of its neutral parent. This in turn is smaller than the sum of the cross-sections of its atomic components. The cross-sections of atomic C, N, O, F and Ne are  $\sim 10^{-17} \text{ cm}^2$ , and that of

H is  $\sim 3 \times 10^{-18} \text{ cm}^2$ , for ionisation by protons and electrons having  $\beta \sim 0.14$ . Thus all the molecular ion species listed in Table 1 will have ionisation cross-sections close to  $10^{-17} \text{ cm}^2$  when moving with  $\beta \sim 0.14$ . This leads to a partial ionisation rate at 1 AU of  $\sim 4 \times 10^{-7} \text{ s}^{-1}$  (taking the density of solar wind as  $10 \text{ cm}^{-3}$ ). At  $\beta \sim 0.14$  the charge exchange cross-section with  $\text{H}^+$  from the solar wind is very small, while the photoionisation cross-section for molecular ions will be smaller (because of the higher ionisation energies) than that of the parent molecules with  $\beta \sim 0$  that have been considered by Siscoe and Mukherjee<sup>8</sup>. Thus the lifetime of the fast moving molecular ions against break-up is hardly dependent on its velocity and remains at  $\sim 10^6 \text{ s}$  at 1 AU, increasing as the square of the distance from the Sun. We therefore conclude that the likely lifetime of suitable molecular ions, such as  $\text{CO}^+$ , is adequate for a reasonable survival probability through the whole acceleration and diffusion stages proposed by Fisk *et al.*<sup>4</sup>. There is thus a reasonable chance of detectable fluxes of certain molecular ions with energies in the region of 10 MeV per nucleon.

From these considerations we feel that cometary material may have an important role as part of the source material for the anomalous component and that molecular ions from such a cometary source may be present in the anomalous component. The method of particle identification used in instruments to date means that this last point could not be confirmed. The method uses two measurements, the rate of energy loss  $dE/dx$  and the total energy,  $E$ . For a molecule these are proportional to  $\sum Z_i^2$  and  $\sum A_i$  respectively since each component atom has the same incident velocity ( $Z_i$  and  $A_i$  are the atomic number and mass of the  $i$ th component). Thus  $\text{OH}^+$  closely resembles  $\text{O}^+$ , and  $\text{CO}^+$  will lie between  $\text{Ne}^+$  and  $\text{Na}^+$  in the data from these detectors. The most clearcut way of establishing that an individual event is a molecular ion involves the determination of  $dE/dx$  at several different energies covering the whole range of a stopping particle. For molecules consisting of different atoms, for example  $\text{CO}^+$ , the different range of each component produces a distribution of  $dE/dx$  plotted against depth having two (or more) maxima. For the important case of molecules containing hydrogen such as  $\text{OH}^+$  the range of the proton will often be sufficiently large to cause the event to be ignored unless special precautions are taken to recognise such events.

Recent high precision experiments on the ISEE and Voyager spacecraft<sup>9-11</sup> do not seem to have sufficient range discrimination to identify a molecular ion in this way. However, the high precision with which  $dE/dx$  and  $E$  are measured in these experiments should enable these molecular ions to be recognised as a group apparently having an anomalous mass, for example,  $\text{CO}^+$  would appear to be  $^{28}\text{Ne}$  and  $\text{OH}^+$  would appear to be  $^{17,25}\text{O}!$

If fluxes of molecular ions are reasonably high, a considerable number of different species could probably be detected. Their relative abundance would give valuable insight into processes associated with the injection of material and its acceleration to produce this particular low energy component of the cosmic radiation.

## Increase of X-ray reflection intensities and profile widths at the low- to high- $\text{V}_3\text{O}_5$ phase transition state

An unexpected increase in peak intensity and profile half width has been observed in an X-ray diffraction experiment for many reflections from a crystal of  $\text{V}_3\text{O}_5$  kept at its phase transition temperature. One explanation of the phenomena is that the 'mosaic structure' of the crystal is altered in the phase transition state, resulting in decreased extinction and increased profile widths. The results presented here are interesting spin off products of crystallographic studies of the mixed-valency oxide  $\text{V}_3\text{O}_5$ . The semiconductor low- $\text{V}_3\text{O}_5$  transforms in a first order transition at  $155^\circ\text{C}$  into high- $\text{V}_3\text{O}_5$ , which is a 'poor metal'<sup>1</sup>. The transformation is instantaneous and reversible and implies that an ordered distribution of V(III) and V(IV) atoms is replaced by an only partially ordered distribution, the changes in the atomic positions being fairly small ( $\leq 0.1 \text{ \AA}$ ). These facts are based on the results of accurate X-ray crystal structure determinations of the two modifications at  $25^\circ\text{C}$  (ref. 2) and  $185^\circ\text{C}$  (ref. 3) respectively. We started diffraction measurements of  $\text{V}_3\text{O}_5$  at or near the phase transition temperature  $t_T$ , using the good temperature-control facility of the available non-ambient-temperature equipment<sup>4</sup>.

We found that for many strong reflections the peak intensity increased drastically when the temperature passed  $t_T$  in either direction (see Fig. 1). Note that the intensity value for any particular strong reflection usually differs very little between the two modifications. The small difference between the crystal structures manifests itself by the presence of many very weak reflections  $hkl$  with  $h+k+l=2n+1$  in low- $\text{V}_3\text{O}_5$  (space group  $P2_1/c$ ) which are all systematically absent in high- $\text{V}_3\text{O}_5$  (space group  $I2_1/c$ ). There is a general small decrease in the reflection intensities as the temperature of the crystal is increased from room temperature to just below  $t_T$  dependent on increased thermal motions of the atoms. However, the relative intensity decrease is considerably larger for reflections  $hkl$  with  $h+k+l=2n+1$  than for the rest. Therefore a (minor) continuous structural change of low- $\text{V}_3\text{O}_5$  with temperature should precede

**Fig. 1** Peak intensity of reflection 020 recorded with increasing and decreasing temperature respectively. Hysteresis effect is  $1^\circ\text{C}$ . A PAILED X-ray single crystal diffractometer (inclination geometry) was used with  $\text{MoK}\alpha$  radiation (graphite monochromator). The specimen crystal had an approximately cubic shape, the edge being about  $0.17 \text{ mm}$ . It was heated by hot nitrogen gas blown directly on to the crystal. The delivery and heating of the gas, and the temperature control were accomplished by a specially developed device<sup>4</sup>.

the discontinuous change at  $t_T$ . Thus, the difference around  $t_T$  between the two modifications of  $V_3O_5$  is probably even smaller than stated above.

The unit cell dimensions of low- $V_3O_5$  at 25 °C are<sup>5</sup>  $a = 9.859(1)$ ,  $b = 5.0416(5)$ ,  $c = 6.991(1)$  Å and  $\beta = 109.478(6)^\circ$ . The changes from low- $V_3O_5$  at 150 °C to high- $V_3O_5$  at 160 °C are<sup>6</sup>  $\Delta a = -0.13\%$ ,  $\Delta b = -0.18\%$  and  $\Delta c = 0.13\%$ . The close similarity between the unit cell dimensions of the two phases made the positions of the reflections, especially the low-angle ones, shift very little in crystal rotation angle  $\omega$  at the transition, which was important for the initial observation of the effect.

One explanation of the phenomenon is that the rearrangement disorder in the transition state reduces the degree of perfection of the crystal with decreased extinction as one result. To test this hypothesis, many reflections with severe extinction in different directions of the reciprocal space were investigated. The intensity increase at  $t_T$  was always observed, at least for  $y \leq 0.9$ ,  $y$  being the secondary extinction correction factor calculated according to Zachariasen<sup>7</sup>, and  $y = I_{\text{obs}}/I_{\text{corr}}$  where  $I$  is the integrated intensity. Table 1 presents some of the studied reflections.

Although some of the strongest reflection intensities could be expected to suffer from counting losses no corrections were

Fig. 2 Intensity profiles ( $\omega$ -scan) for reflection  $-114$  observed below (L) and above (H)  $t_T$  and constructed at (T)  $t_T$  from point observations (\*). Experimental conditions as in Fig. 1.

$\nu$  is the inclination angle of the detector axis,  $Y$  the angle between the detector axis and a horizontal plane containing the primary beam and the crystal rotation axis ( $//[001]$ ). The  $y$ -values actually refer to H but should be almost identical for L.

applied. However, this would mean that the real effect in these cases was even larger than the one observed.

If the crystal perfection is decreased in the phase transition state one should also observe a broadening of the width of the integrated intensity profile. Accordingly, comparative measurements of the half widths of these profiles for the reflections included in Table 1 were made just below  $t_T$ , at  $t_T$  as well as just above it. The measurements at the phase transition temperature were difficult to perform, and the time available for each of them usually was between 5 and 10 s. However, as the actual reflections had strong intensities, using the pen recorder as the intensity indicator was successful. In all cases investigated, the reflection profile more or less broadened at  $t_T$  (see Fig. 2 and Table 1). This quantity is a multiple convolution of a number of experimental components of which all but one or possibly two crystal mosaicity components, isotropy being assumed, should be fairly constant for each reflection at and around  $t_T$ . An attempt will be made to correlate the observed half width increases at  $t_T$  with the theoretical expressions for the mosaic angle distribution half width and the mosaic particle size component half width, which have both been derived by Ito<sup>8</sup>. However, a deconvolution analysis is necessary for this which is still in progress.

Similar effects of other comparable phase transitions do not seem to have been discussed previously. However, the transient intensity increase of a strong reflection at the  $\alpha$ - to  $\beta$ -quartz transition which is shown in ref. 9 may be another example.

## Measurement of the neutron spectra from beam-heated PLT plasmas

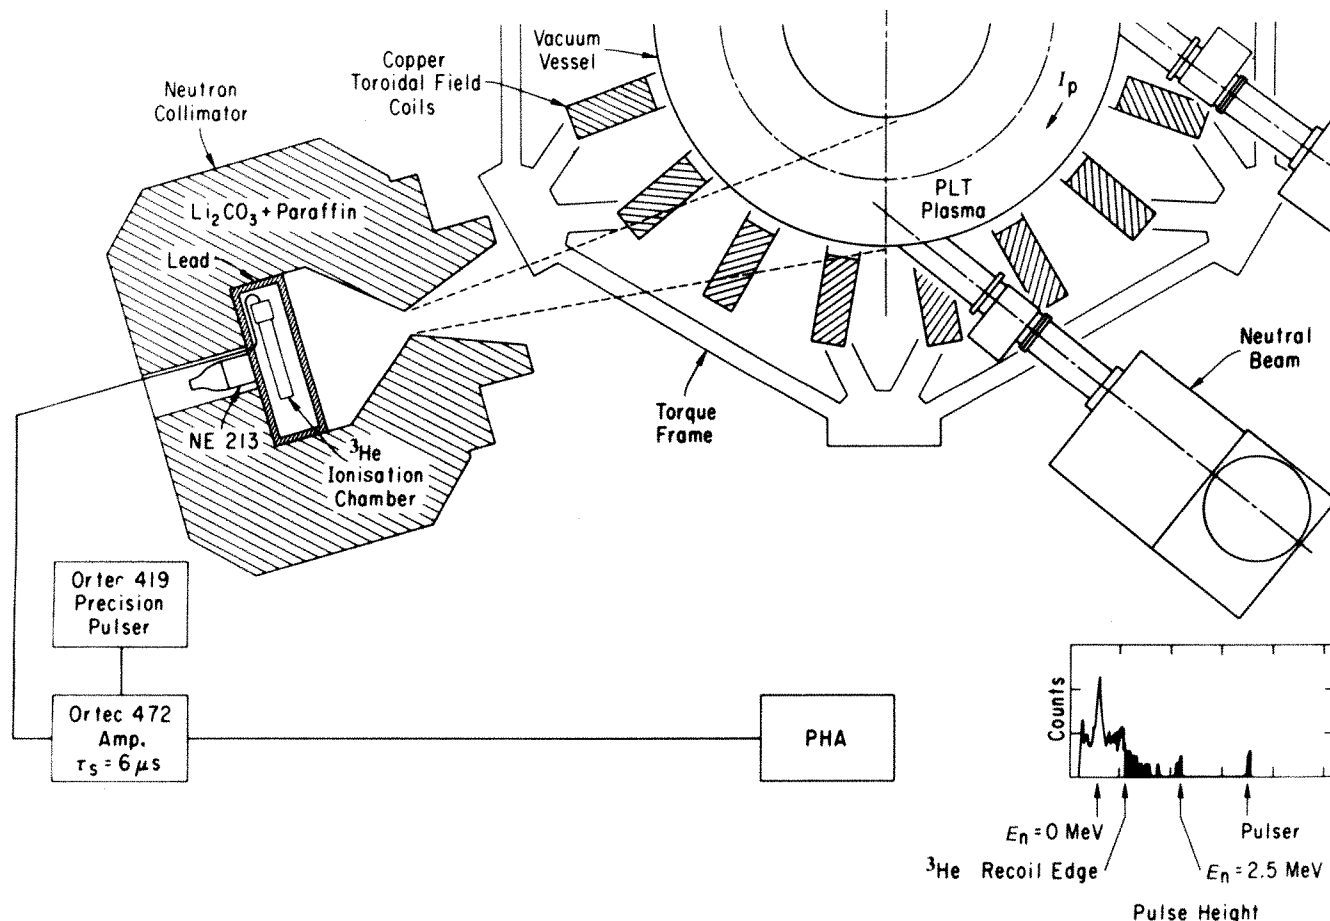

MEASUREMENTS of the neutron spectra from the PLT tokamak plasma are reported here which provide information on the centre-of-mass velocity of the reacting deuteron pairs. The observation in PLT of no significant directed velocity yields additional evidence that the neutrons are produced by a thermonuclear process. Previous spectral measurements on other fusion devices have often determined that the neutron emission was non-thermonuclear and resulted from a small 'tail' component of energetic ions<sup>1-3</sup>. The neutron spectra indicated a directed velocity of the reacting deuterons and thus non-thermonuclear neutron emission if the injected neutral beam ions were deuterium. In this condition, the neutron spectra were consistent with the expected beam-induced  $d(d,n)^3\text{He}$  reactions. However, if the heating beam used hydrogen, then the neutron spectra are consistent with a thermonuclear neutron emission resulting from the beam heating of the bulk deuterons in the plasma.

The importance of a thermonuclear neutron emission is that it allows the neutron emission measurement to be used to deduce ion temperature<sup>4</sup>. The ion temperature deduced by the magnitude of the neutron emission has been consistent with other PLT ion temperature diagnostic<sup>5,6</sup> such as charge exchange spectral observations. Although the charge exchange spectrum indicated a maxwellian ion population up to 6 T, the observation had been made only perpendicularly to the direction of the tangential neutral beam injection. Thus, we use the neutron spectral measurements to provide information on the plasma ion population in the direction parallel to the neutral beam injection where non-thermonuclear emission might be induced by the

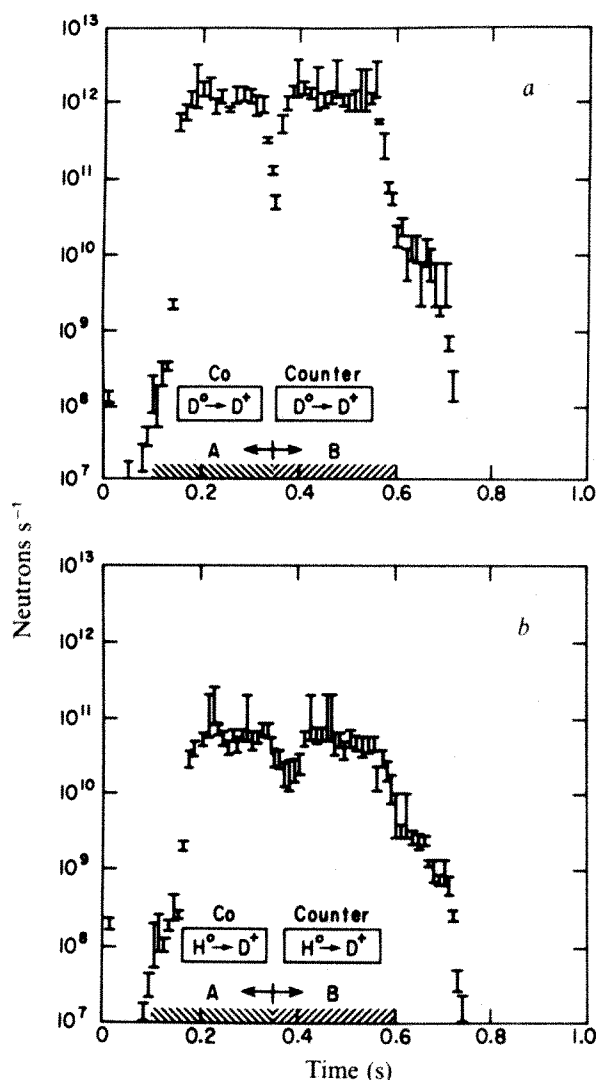

presence of trace amounts of deuterium in the hydrogen beams or by momentum transfer from the beams to the background plasma. To observe such asymmetries, a neutron spectrometer was collimated (Fig. 1) to look towards co-injected ions and comparisons were made between co-only injection and counter-only injection. In this manner, any non-thermonuclear emission induced by the beams would be observed from the shift of the mean neutron energy caused by the directed centre-of-mass velocity of the reacting deuteron pairs. Thus, the PLT neutron spectra experiment was carried out in the manner of the classic neutron spectra experiments on Zeta<sup>1</sup>. All the PLT spectra have about as many counts as in those Zeta spectra, although for PLT the spectra were obtained with time resolution and with higher energy resolution.

The PLT tokamak<sup>7</sup>, and its operation<sup>5</sup> with neutral beams have been described elsewhere. For these experiments, the plasma had a minor radius of 0.40 m as defined by carbon limiters, a major radius of 1.34 m, a toroidal magnetic field of 3.2 T, a plasma current of 0.4 MA, and titanium gettered vacuum walls. Four tangential neutral beams which can collectively deliver up to 2.5 MW of power to the plasma were used. Two of the beams (co) were directed parallel to the plasma current, and two (counter) were directed antiparallel to the plasma current.

About 200 discharges were run with hydrogen neutral beam injection into a deuterium plasma ( $\text{H}^0 \rightarrow \text{D}^+$ ) and about 15 discharges were run with deuterium neutral beam injection into a deuterium plasma ( $\text{D}^0 \rightarrow \text{D}^+$ ). In each set of discharges, the co-injectors were used early in the discharge and the counter-injectors were applied later in the same discharge after the co-injectors were turned off and the neutron emission from them had decayed. The neutron emission (Fig. 2) was about  $7 \times 10^{10} \text{ n s}^{-1}$  during the hydrogen injection ( $\text{H}^0 \rightarrow \text{D}^+$ ) and about  $10^{12} \text{ n s}^{-1}$  during the deuterium injection ( $\text{D}^0 \rightarrow \text{D}^+$ ). For the  $\text{D}^0 \rightarrow \text{D}^+$  cases, only one beam at reduced voltage was used to

**Fig. 1** The  $^3\text{He}$  ionisation chamber is surrounded by two inches of lead to reduce X-ray induced counts and is collimated by a 7-ton paraffin plus  $\text{Li}_2\text{CO}_3$  neutron collimator to view tangentially to the PLT minor axis.

**Fig. 2** The neutron emission during (a)  $D^0 \rightarrow D^+$  (about 0.3 MW in each direction) and (b)  $H^0 \rightarrow D^+$  (about 0.9 MW in each direction). The detector counting intervals were made to coincide with A, co-only injection; and B, counter-only injection. The ion temperature deduced from the magnitude of the neutron emission ( $H^0 \rightarrow D^+$ ) is about 2 keV.

keep the neutron emission low and thus prevent the neutron spectrometer from saturating.

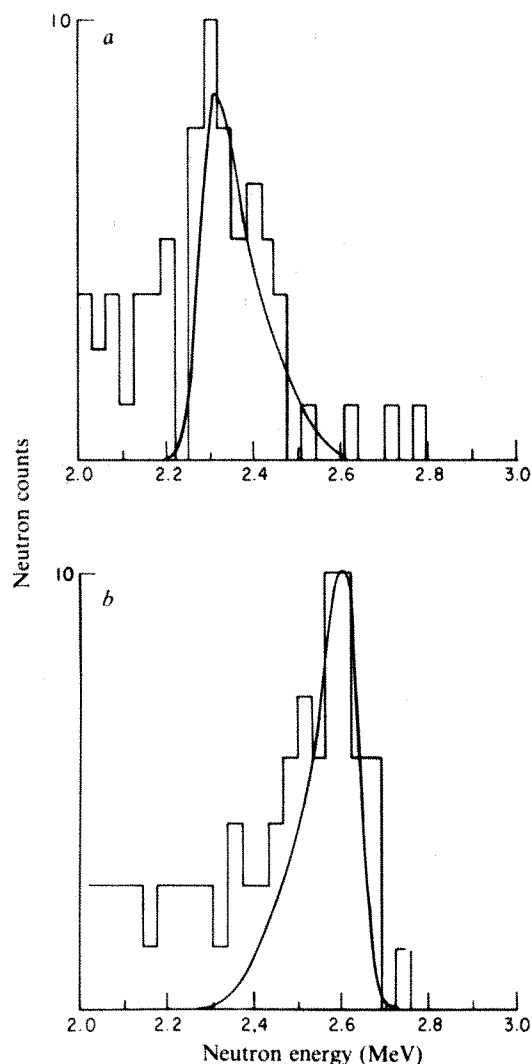

The neutron spectra were recorded by a  $^3\text{He}$  ionisation chamber (Fig. 1) and the counts were recorded separately for two different time zones during the discharge. The first time zone encompassed and recorded the co-only injection. The second time zone encompassed and recorded the counter-only injection. The early and end stages of the discharge were excluded to remove any possibility of X-ray noise induced by runaway electrons. All the discharges reported here were quite free of runaway electrons.

The neutron collimator, which is similar to one used by Glasgow *et al.*<sup>8</sup>, is composed of equal weights of paraffin and  $\text{Li}_2\text{CO}_3$  to a linear dimension of about nine absorption lengths for 2.5 MeV neutrons. The paraffin thermalises the neutrons incident on the collimator from directions other than the observation volume, and the  $^6\text{Li}$  in the natural lithium of the  $\text{Li}_2\text{CO}_3$  non-radiatively absorbs the thermal neutrons. Tests of the collimator with the observation window plugged, indicate that  $<10^{-3}$  of the total spectrometer counts occur from neutrons incident on the  $^3\text{He}$  detector from unobserved regions. The complex PLT geometry (Fig. 1) enables many neutron scattering centres to be within the line of sight, such as the massive copper coils, diagnostic equipment, and the concrete wall on the far side of PLT. These scattering centres have an unknown influence on

the recorded neutron spectra and should introduce low energy neutrons into the spectra.

The  $^3\text{He}$  ionisation chamber<sup>9,10</sup> collects the charge produced by the proton and triton in the  $^3\text{He} (n,p)t$  reaction. The detector saturates at total count rates of about  $10^4$  c.p.s., but even near saturation, only a few c.p.s. are recorded in the region near 2.5 MeV. For each  $^3\text{He} (n,p)t$  count near 2.5 MeV, there are many more  $^3\text{He}$  recoil counts, and  $^3\text{He} (n,p)t$  counts for scattered neutrons which have reached epithermal energies (spectrum in Fig. 1). The absolute energy scale was derived from the  $Q$  of the  $^3\text{He}$  reaction (0.76 MeV) and the linear response of the spectrometer. This procedure could result in the energy scale of the set of spectra being in error by  $\pm 0.05$  MeV in the region near 2.5 MeV. The spectrometer was calibrated using accelerator induced mono-energetic neutrons and has an energy resolution of about 0.055 MeV FWHM, or standard deviation of a single count. The ability of the spectrometer to determine relative mean energies should be limited only by statistics.

The  $D^0 \rightarrow D^+$  spectra (Fig. 3) indicate an energy shift of 0.26 MeV between co-only and counter-only injection, establishing the ability of the  $^3\text{He}$  detector to make noticeable neutron energy shift measurements in the PLT conditions. Each of these  $D^0 \rightarrow D^+$  spectra can be reasonably explained by the expected beam-induced reactions between the energetic injected ions and the background thermal ions. The PLT  $D^0 \rightarrow D^+$  spectra were compared to  $Z_{\text{eff}} = 5$ ,  $T_i = 1.5$  keV Monte Carlo

**Fig. 3** The measured  $D^0 \rightarrow D^+$  neutron spectra. The counter-injection voltage was 30 kV (a). The co-injection voltage was 26 kV (b).

Fig. 4 The measured  $H^0 \rightarrow D^+$  neutron spectra including all the co-only and counter-only counts.

code predictions<sup>11</sup> for the collimated neutron spectra (Fig. 3). The co-injection case indicated a 60%  $\chi^2$  probability of being produced by beam-induced reactions while the counter-injection case indicated a 55%  $\chi^2$  probability of being produced by beam-induced reactions. The  $\chi^2$  test was performed only for that part of the calculated spectrum which was  $>10\%$  of the peak.

The  $H^0 \rightarrow D^+$  spectra indicate no statistically significant energy shift between the co-only and counter-only injection cases, as is expected for thermonuclear neutron emission. The predicted mean energy should be 2.45 MeV, while experimentally, the 11 co-only counts have a mean energy of  $2.41 \pm 0.02$  MeV and the 19 counter-only counts have a mean energy of  $2.42 \pm 0.01$  MeV. The downward energy shift from 2.45 MeV probably results from the energy scale calibration. The expected line width should be 0.12 MeV for the 2 keV ion temperature plasma measured by a detector with 0.055 MeV resolution. Adding all the experimental  $H^0 \rightarrow D^+$  counts together to improve the statistics (Fig. 4) results in a line width of 0.13 MeV. The observed  $H^0 \rightarrow D^+$  neutron spectrum indicated a 50%  $\chi^2$  probability of being produced by thermonuclear reactions. One degree of freedom was used in the  $\chi^2$  test to normalise the mean of the spectra and the fit was applied only for that part of the calculated spectrum  $>10\%$  of the peak.

In conclusion, no measurable centre-of-mass velocity of the reacting deuteron pairs was induced by hydrogen neutral beam injection. Furthermore, the shape of the experimental neutron emission line was consistent with a thermonuclear neutron emission at the ion temperature predicted by the magnitude of the neutron emission. These two observations are consistent with a thermonuclear origin of the PLT neutrons during hydrogen neutral beam heating of a deuterium plasma.

We thank J. Boychuk, W. Mycock, M. Perron and the PLT crew for experimental help. The neutron spectrometer was tested at RTNSI with the help of D. Slaughter. This work was supported by the US Department of Energy, Contract no. EY-76-C-02-3073. L.S. is from Exxon Nuclear Co. and R. S. from Westinghouse Corporation.

## Deposition and accumulation of plutonium isotopes in Antarctica

DATA on the deposition of plutonium isotopes are presented here from the atmosphere at Dome C ( $123^{\circ}10' E$ ,  $74^{\circ}39' S$ ; 3,214 m elevation) on the high Antarctic plateau. Plutonium isotopes are among the anthropogenic chemicals that have become global contaminants<sup>1–3</sup> and it is, therefore, important to gain a historical perspective to their worldwide dispersion. The analysis of successive layers of permanent snow fields permits the determination of both present and historical fluxes of anthropogenic chemicals and other contaminants that are dispersed through the atmosphere<sup>3–6</sup>. Dome C is an ideal site for such studies: annual precipitation at Dome C is of the order of  $3.7 g H_2O cm^{-2}$  (ref. 7), considerably lower than the mean annual deposition of  $15.5 g H_2O cm^{-2}$  over the entire continent<sup>8</sup>. The mean annual temperature is  $-53.5^{\circ}C$ , with summer temperatures remaining well below freezing, precluding vertical percolation through successive layers and reducing potential losses from volatilisation.

A 5 m pit was dug at Dome C in January 1977. Snow in layers of approximately 10 cm was sampled and the meltwater was transferred into 20-l, polyethylene cubitainers. They were then acidified, equilibrated, and the isotopes subsequently co-precipitated with aluminium phosphate following the technique of Koide and Bruland<sup>9</sup>. Each sample consisted of a total of 100 litres. The precipitates in the original cubitainers were returned to the US. They were dissolved in 9 M HCl and the Pu isotopes isolated following the procedures of Talvitie<sup>10</sup> and Wong.<sup>11</sup> An aliquot was removed for  $^{210}Po$  determination<sup>9</sup>. Samples were counted within 2 weeks after separation by  $\alpha$  spectrometry;  $^{208}Po$  and  $^{242}Pu$  were used as yield tracers.

Figure 1 shows the activities of  $^{239+240}Pu$  and  $^{238}Pu$  versus depth of snow. Assignment of the 1955 time horizon to 214 cm, at the beginning of the rise in  $^{239}Pu$  activity, was based on previous work at Dome C by Lorius<sup>7</sup> and studies undertaken elsewhere in Antarctica<sup>12–14</sup> which have shown a sharp increase in  $^{90}Sr$  and gross  $\beta$  activity in strata deposited in early 1955. This assignment is consistent with our  $^{210}Pb$  results. Assuming constant sedimentation for the depth interval, 0–250 cm,  $^{210}Pb$  activity at any depth  $z$ ,  $A_z$ , can be expressed by  $A_z = A_0 \exp(-\beta z)$ . Our data yielded an  $A_0$  of 142 d.p.m. per 100 litres and a  $\beta$  of  $-0.00308 cm^{-1}$ , where  $r = 0.90$  for the best-fit curve. Thus, a time interval of  $21.2 \pm 2.4 yr (1\sigma)$  to this 214 cm depth was calculated. Our assignment of the 1965 time horizon interval was derived by interpolation and estimates of maximum error due to compaction<sup>15</sup>.

The profile of  $^{239+240}Pu$  deposition (Fig. 1a) is unlike the profile observed in Greenland<sup>7</sup> in that the majority of the total fallout occurred before 1960, whereas in Greenland the greater portion of the deposition occurred after 1960. Significant quantities of  $^{239+240}Pu$  began to appear in the snow layer corresponding to the estimated date of 1955. The ensuing peak's size and timing suggest that a significant portion of the  $^{239+240}Pu$  could have been contributed by the US Castle test, Bravo, on 28 February 1954, at Bikini ( $165^{\circ} E$ ,  $11^{\circ} N$ ). This 15 megatonne detonation derived a major portion of its energy from the

fusion-induced fission of  $^{238}\text{U}$  (ref. 16). Large quantities of  $^{239}\text{Pu}$  were probably produced from  $^{238}\text{U}$  by neutron capture. Previous studies<sup>12-14</sup> have shown that significant stratospheric fallout from this test began to arrive in the Antarctic  $12 \pm 2$  months later. Further weapons tests at Bikini and Eniwetok such as the Hardtack series during 1958 might have contributed additional  $^{239+240}\text{Pu}$  to this major peak.  $^{90}\text{Sr}$  attributed to these tests has been observed at several Antarctic sites with an arrival date of early 1959<sup>13</sup>. The smaller amounts of  $^{239+240}\text{Pu}$  deposited at Dome C after 1960 suggest that the tests conducted in the early 1960s, primarily in the Northern Hemisphere, resulted in a relatively low level of stratospheric transfer to the high latitudes of the Southern Hemisphere.

**Fig. 1**  $^{239+240}\text{Pu}$  (a) and  $^{238}\text{Pu}$  (b) activities at Dome C, Antarctica. Horizontal lines depict the depth of each layer sampled. Vertical lines within each sample represent the uncertainty due to counting statistics ( $1\sigma$ ). Plutonium sample counting times ranged from 2 to 9 d. The minimum detectable amount of  $^{238}\text{Pu}$  and  $^{239+240}\text{Pu}$  was found to be of the order of 0.03 d.p.m. per 100 litres. Samples for the depth intervals, 11.9–23.9 cm, 48.0–59.9 cm, and 71.9–83.8 cm were not obtained.

Figure 1b shows the snow record of  $^{238}\text{Pu}$  at Dome C. The April 1964 burnup of a satellite (SNAP-9A) containing 17 kCi of  $^{238}\text{Pu}$  in the Southern stratosphere<sup>1</sup> is recorded as a rapid activity increase in the 1965–66 stratum. The deposition of  $^{238}\text{Pu}$  closely parallels the changes in the stratospheric inventory of SNAP  $^{238}\text{Pu}$  over the period 1964–69 as shown by Harley<sup>17</sup>. The activity ratio of  $^{238}\text{Pu}/^{239+240}\text{Pu}$  also rises sharply, reaching a maximum of 150% in the layer assigned to approximately 1967 (the stratum following the peak activity). Harley<sup>17</sup> reported comparable high activity ratios in Southern Hemisphere surface air samples in 1967 and 1968.

During the period of peak fallout of  $^{239+240}\text{Pu}$  (1955–59), levels of  $^{238}\text{Pu}$  activity were markedly low ( $^{238}\text{Pu}$  values of  $0.10 \pm 0.02$  and  $0.12 \pm 0.03$  d.p.m. per 100 litres compared to the respective  $^{239+240}\text{Pu}$  values of  $56.2 \pm 1.3$  and  $28.4 \pm 1.2$  d.p.m. per 100 litres). Harley<sup>17</sup> suggested that a  $^{238}\text{Pu}/^{239+240}\text{Pu}$  ratio of 3% might be representative of weapons fallout. If this was the case, then a significant  $^{238}\text{Pu}$  peak should have been associated with the maximum fallout of  $^{239+240}\text{Pu}$ . However, this was not observed, and in fact, the activity ratio was of the order of 0.3%, an order of magnitude lower. Harley<sup>17</sup> pointed out that the value of 3% was not well established since good  $\alpha$  spectrometry was not available on their samples before SNAP-9A. Thus, this ratio may be doubtful as a widely applicable value. This discrepancy warrants further investigation.

To calculate the fluxes of  $^{239+240}\text{Pu}$  and of  $^{238}\text{Pu}$ , a mean density of  $0.352 \text{ g cm}^{-3}$ , derived from the data of Lorius<sup>7</sup> was used. The flux of  $^{239+240}\text{Pu}$  was calculated by integrating over the depth interval 0–222.5 cm. This value was found to be  $90.4 \text{ d.p.m. m}^{-2}$ , while the peak of  $19.2 \text{ d.p.m. m}^{-2} \text{ yr}^{-1}$  occurred during 1956–57. Similarly, after decay correction the flux of  $^{238}\text{Pu}$  was determined to be  $14.4 \text{ d.p.m. m}^{-2}$ . The peak flux of  $3.22 \text{ d.p.m. m}^{-2} \text{ yr}^{-1}$  occurred around 1965–66. Hardy *et al.*<sup>1</sup> using soil data have estimated cumulative worldwide fallout of plutonium isotopes as a function of latitude. Their estimates for  $70\text{--}80^\circ \text{S}$ , based on extrapolation from Southern Hemisphere samples, were  $0.03 \pm 0.01 \text{ mCi km}^{-2}$  of  $^{239+240}\text{Pu}$  and  $0.008 \pm 0.005 \text{ mCi km}^{-2}$  of  $^{238}\text{Pu}$  derived from SNAP-9A. Our results provide corresponding values of 0.04 and 0.006, respectively, in good agreement with the estimates cited above.

The profiles of Fig. 1 suggest that almost all of the plutonium isotopes injected into the atmosphere have now been removed. The activities of both  $^{239+240}\text{Pu}$  and  $^{238}\text{Pu}$  deposited during 1976 at Dome C were only 1.4% of the activities deposited during the respective periods of maximum fallout.

## Climate and thermodynamic systems of maximum dissipation

THE Earth-atmosphere is a classic example of a closed, dissipative and nonlinear thermodynamic system which is subject to both regular and irregular impulses causing significant departure from steady state. It is closed because it exchanges energy (solar and thermal radiant energy) but not mass with its environment. It is dissipative because the net input of radiant energy occurs mainly in regions of high temperature towards the Equator and the net output occurs mainly in regions of low temperature towards the poles. It is nonlinear basically because of the multiplicity of internal feedbacks and because of the importance of advective processes. It has steady-state character in the sense that the annual mean radiant energy input is very close to the annual mean output, and parameters such as the annual mean temperature do not vary significantly from one period to another. The regular seasonal variation in solar position ensures significant departure from the steady state so defined, and there are also significant irregular departures arising (for instance) from variations of solar input and IR output caused by variations in the amount and distribution of cloud. Recently I have shown<sup>1</sup> that the overall Earth-atmosphere climate system seems to have adopted a format whereby the total thermodynamic dissipation associated with the horizontal energy flows in the atmosphere and ocean is a maximum. 'Format' in this context refers to the annual average geographic distribution of cloud, surface temperature and the horizontal energy flows. The practical significance of this is that, if one could accept it as a general principle governing climate behaviour, one could use it directly as a means of *a priori* prediction of climate and climate change without needing detailed analysis of the internal workings of the system. I could not explain previously why the Earth-atmosphere system should be so constrained. This note points out that the Earth-atmosphere has characteristics such that it might be expected to obey such a constraint. Furthermore, these characteristics are sufficiently general that the same principle of selection of steady-state mode of maximum dissipation may apply to a broad class of non-linear systems.

A fair thermodynamic representation of the global climate system is as depicted by the solid lines in Fig. 1. There is an input of solar energy  $I$ , most of which is converted directly into various forms of internal energy  $IE$  and is returned to space in the form of thermal IR radiation. Some of the input appears as available potential energy  $P$ , is converted to kinetic energy  $K$ , and is in turn dissipated by friction into internal energy before being radiated back to space. At steady state the rates of creation of

**Fig. 1** The total Earth-atmosphere system of: energy transfers (thin solid lines); reservoirs of internal, available potential, and kinetic energy ( $IE$ ,  $P$  and  $K$  respectively); feedback controls from kinetic energy (dashed lines); and an indication of the non-linearity of the rate of potential energy conversion (dashed diode symbol). Adequate data are not yet available for the oceanic part of the total system, but for the atmospheric component the annual average quasi-steady state values are:  $i_1 = i_2 = i_3 \approx 2.3 \text{ W m}^{-2}$ ;  $K \approx 1.5 \times 10^6 \text{ J m}^{-2}$  with the ratio  $P:K \approx 10:1$  (refs 2, 7).

available potential energy, conversion of available potential to kinetic energy and the dissipation of kinetic energy ( $i_1$ ,  $i_2$  and  $i_3$  respectively) are equal.

The dashed components of Fig. 1 concern two characteristics of importance to the present argument. First, there are feedbacks such that both the rate of energy input ( $I$  or  $i_1$ ) and the rate of dissipation  $i_3$  are functions of, or can in principle be related to, the total kinetic energy. (One of the prime controls on the rate of energy input is, for instance, cloud cover; and cloud cover is a complex function of the amount and distribution of the large and small-scale motions of the atmosphere and ocean, of quantities which determine the motion, or of quantities which are determined by the motion.) Second, the rate of conversion  $i_2$  of potential to kinetic energy is a highly non-linear and increasing function of potential energy. Some examinations of the process effectively envisage an  $i_2 = (P - P_c)^n$  relation where  $P_c$  is some critical value of potential energy below which the rate of conversion is very small<sup>4</sup> and  $n > 1$ .

Let  $i_1$  and  $i_3$  be functions of kinetic energy as in Fig. 2. The actual shape of the curves is irrelevant. The important characteristics are: (1) There is the possibility of a number (and in the case of the Earth-atmosphere system, a large number) of steady state positions where the rate of energy input equals the rate of output (that is  $i_1 = i_3$ ); and (2) the dissipation rate  $i_3$  is an increasing function of kinetic energy.

The real system is sufficiently complex in its detailed interactions for there to be considerable natural variability in, for instance, cloud cover and the rate of energy input. Therefore there is variability about whatever is the steady state determined by the current average value of  $K$ . The extent and character of this variability is unknown even for the quasi-steady state which the Earth-atmosphere system presently occupies. However, consider at some stage that the system was in one of the mid-range stable regimes (A of Fig. 2 say). The input  $I$  or  $i_1$  will be subject to natural variability which may or may not be random and is not necessarily a function of  $K$ , but may occasionally be large enough to boost the system to another stable regime. If the variability is random, presumably an impulse of  $+\Delta Q$  in  $i_1$  is as likely to occur as an impulse of  $-\Delta Q$ , and in the absence of other information the system is as likely to change to a new steady state of lower average  $K$  as to one of higher average  $K$ .

However, the non-linearity of the conversion of  $P$  to  $K$  ensures that for large values of  $\Delta Q$  (short term changes of  $i_1$  away from its steady state value where they are not necessarily an immediate function of  $K$ )

$$\frac{\Delta K^+}{\Delta Q} > \frac{\Delta K^-}{-\Delta Q} \quad (1)$$

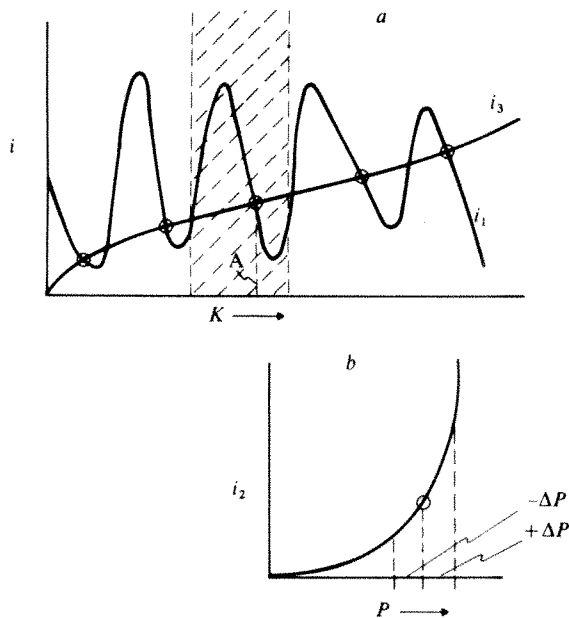

That is, a positive impulse  $\Delta Q$  in  $i_1$  is more likely to change the system to a steady state of higher average  $K$  (and dissipation) than is a negative impulse in  $i_1$  likely to change the system to a steady state of lower average  $K$ . This is obvious (see legend to Fig. 2) but is not easy to prove in a rigorous manner. A complete analysis would require a fairly sophisticated application of control theory. (It would require knowledge of the exact form of the random (?) impulses, and some specific knowledge of at least the statistical distribution of steady states as a function of  $K$ . Such information is not yet available for the Earth-atmosphere system.) Suffice it to say that first order treatment leads to the relationship

$$\frac{\Delta K^+}{\Delta Q} - \frac{\Delta K^-}{-\Delta Q} \approx \frac{b\epsilon}{1 + 2cZ + c\epsilon + c^2 + c^2Z^2 + c^2Z\epsilon} \quad (2)$$

where, if  $\Delta t$  is the short time period over which the impulse is applied and  $a$  is the average slope of the  $i_3$  versus  $K$  relationship and  $\Delta P$  or  $-\Delta P$  are the net responses in available potential energy to  $\Delta Q$  or  $-\Delta Q$  respectively, then

$$b = \frac{1}{2}\Delta t / (1 + \frac{1}{2}a\Delta t); \quad c = \frac{1}{2}\Delta t; \quad Z = \Delta i_2 / (-\Delta P);$$

and  $\epsilon = \Delta i_2 / \Delta P - \Delta i_2 / (-\Delta P)$

**Fig. 2** *a*, The functions relating average rate of energy input  $i_1$  and the rate of dissipation  $i_3$  to the average total kinetic energy  $K$ . The circled points are possible stable steady states. The uncircled points where  $i_1 = i_3$  are unstable steady states because of the positive feedback associated with slight displacements of  $K$ . The hatched area roughly indicates the extent of the stable regime about one such steady state  $A$  (that is between the adjacent unstable steady states). The central question is why short-term random variability of  $i_1$  about the average value determined by  $K$  should (if the impulses are large enough) preferentially boost the system to steady states of higher average  $K$  and ultimately to maximum  $i_3$  or dissipation. The basic reason for the system under discussion is super-linearity in the rate of conversion  $i_2$  of available potential energy  $P$  (see *b*). Sub-linearity would tend to ensure movement to steady states of lower average  $K$ . The intuitive argument (see text) is as follows:  $+\Delta Q$  on  $i_1 \rightarrow$  growth of  $P \rightarrow$  much increased  $i_2 \rightarrow$  large growth of  $K$ .  $-\Delta Q$  on  $i_1 \rightarrow$  decay of  $P \rightarrow$  slightly decreased  $i_2 \rightarrow$  slight decay of  $K$ .

Note that the changes  $\Delta i_2$  in  $Z$  and  $\varepsilon$  refer to the result of changes  $\Delta P$  and  $-\Delta P$  away from the steady state value of  $P$ . Thus, if one accepts  $\Delta K^+ / \Delta Q - \Delta K^- / (-\Delta Q)$  as a measure of the 'strength'  $S$  of the tendency under random forcing to move to steady states of higher dissipation, then large  $S$  is ensured among other things by greater positive non-linearity  $\varepsilon$  in the rate of conversion of potential to kinetic energy. It is ensured also by smaller slope of the  $i_3$  versus  $K$  relation.

Provided (1) The rate of conversion of  $P$  to  $K$  is a super-linear increasing function of  $P$ ; (2) the rate of dissipation is an increasing function of  $K$ ; (3) the system has several possible stable steady states; and (4) there is random variability in the rate of energy input which is, or was at some time, of sufficient magnitude to boost the system from one steady state to another, then it can be expected that the system will ultimately occupy that steady-state regime which has maximum dissipation. As far as the Earth-atmosphere is concerned all the conditions are acceptable, but are difficult to prove absolutely. In particular, it has yet to be proved that the dynamical constraints on atmospheric and oceanic motions allow the existence of more than one of the steady states otherwise allowable on energy balance considerations alone. Furthermore, the possibility must be considered that the distribution of possible steady states as a function of average kinetic energy is so extraordinary that the mechanism envisaged here is effectively negated.

Note that 'random variability of input' can be occasioned by processes internal to the system. It is not necessary to assume changes in some external parameter such as the solar constant.

In general terms the above limitations are sufficiently broad and non-restrictive to suggest that the overall concept may be applicable to a large class of non-linear thermodynamic systems

where there is 'series' conversion of energy from one form to another. In the Earth-atmosphere example, the non-linearity of the conversion of  $P$  to  $K$  is particularly obvious ( $\varepsilon$  of equation (2) is large) and presumably once the system is in its ultimate format there is no tendency to return to a regime of lower dissipation. However, one can imagine systems where the non-linearity is weak and the ultimate behaviour would be no more than a tendency to spend more time in regimes of higher dissipation. Similarly a system of strongly sub-linear energy conversion (negative  $\varepsilon$ ) would be expected to move towards the stable steady state of minimum dissipation.

The Earth-atmosphere example effectively involves a 'series' system of energy conversions, and the state of maximum dissipation is also the state of maximum rate of energy transfer—a condition which has been the focus of several investigations in this and other branches of fluid mechanics<sup>5,6</sup>.

## Is there any scientific explanation of the paranormal?

THE apparent impossibility of the occurrence of 'paranormal' phenomena has not discouraged their extensive investigation, although there has not been any uniformly accepted validation or explanation by the scientific community. To clarify exactly how difficult ESP phenomena are to explain, it is necessary to place them in the framework of modern science. Explanations of the phenomena have been brought forward which have been claimed to make them more respectable. These explanations must also be looked at from the point of view of modern science and this paper is devoted to that task. In particular we wish to indicate that on theoretical grounds the only scientifically feasible explanation could be electromagnetism (EM) involving suitably strong EM fields. Thus we regard that this paper completes our earlier work<sup>1</sup> where we presented experimental results giving the level of the EM signals emitted by subjects when engaged in supposedly paranormal activity. These EM levels were many orders of magnitude lower than the ones we calculate here as needed to achieve paranormal effects. Taken together the two papers are a strong argument against the validity of the paranormal.

We will start our analysis by applying a criterion to which psychic phenomena and its explanations must conform, that of the conservation of energy (stemming as it does from the underlying symmetry of the forces of nature).

From energy conservation we may roughly assess the amount of energy transfer required to achieve a particular paranormal effect and hence assess its feasibility. The energies associated with reincarnation and precognition cannot be assessed at all; that for materialisation is expected to be of the order of megajoules if reasonably based on the energy required to break the molecular bonds in one mole of a normal material (500 kJ mol<sup>-1</sup>). The energies needed for psychokinesis (PK), spoon-bending and poltergeists is of the order of joules, assuming that the phenomena occur by the gross effects to which they correspond, this being the movement or deformation of macroscopic objects. Finally the phenomena of dowsing, telepathy, distant-viewing, clairvoyance and faith-healing should need only of the orders of millijoules if it is assumed that they

require activation of certain portions of the brain of the subjects involved, though far more energy may need to be emitted by the source of these effects (as in telepathy or psychic healing). Only these latter phenomena can therefore be regarded as feasible, those requiring joules of energy being unlikely though faintly possible, whilst the first three phenomena contradict modern physics.

There are a range of natural energy sources which could be conjectured as being utilised to achieve so-called paranormal effects. Cosmic rays<sup>2</sup>, nuclear beams<sup>3</sup>, neutrinos<sup>3</sup>, gravitons<sup>4,5</sup> or other controls of gravity<sup>4,5</sup> have all been suggested, though they all have such low power levels, survival value or high energy (by factors of about  $10^{20}$ ) required for control as to be completely irrelevant. A fifth force of nature<sup>6,7</sup> explaining solely ESP phenomena would be purely *ad hoc*; faster-than-light particles<sup>8</sup> and advanced potentials<sup>9</sup> invoked to explain precognition have either severe theoretical difficulties<sup>10</sup> or failed to appear<sup>11-14</sup>. Higher dimensions for materialisation and precognition<sup>15,16</sup> would be *ad hoc* as well as destroying the renormalisation program in quantum field theory.

None of the previous seven approaches suggest any mechanism by which human activity can bring about the desired paranormal phenomena. This is obviously not the case with theories in which the mind is independent of the body to some degree, such as those of Eccles<sup>17,18</sup> and Popper<sup>19,20</sup>, whose papers appear to contain no falsifiable statements.

Numerous attempts have been made to use the difficulties associated with measurements in quantum mechanics to explain paranormal phenomena<sup>21-23</sup>. However, there seems to be considerable confusion in the motivation for these attempts, especially as the standard statistical interpretation of quantum mechanics<sup>24,25</sup> has none of the claimed paradoxes. For paranormal effects to be explained in such a way they must contradict traditional quantum mechanics at some point, for which there is no other evidence.

From the viewpoint of modern science, the most reasonable approach to explain ESP, is electromagnetism (EM). We have previously reported<sup>1</sup> an extensive programme both of detection of EM radiation from subjects over nearly the whole spectrum and human body sensitivity to low-level EM radiation over a restricted, though very relevant, frequency range. We concluded that, for the subjects investigated and the phenomena associated with them (metal-bending, dowsing, psychic healing, telepathy and distant-viewing) EM cannot explain the effects. All the successful cases of PK<sup>1</sup> turned out to be completely explicable either by electrostatics or heat; we will not consider them here.

We shall now detail how difficult, if not impossible, it is for EM to account for ESP phenomena other than PK in the above-mentioned ways.

The human body is nearly a black body of temperature of 310 K that otherwise emits non-black-body EM radiation over a restricted range of physiological frequencies (d.c. to 5–6 kHz). As part of its black-body activity, the body radiates heat, mainly in the near infrared frequencies at wavelengths of  $\sim 10\ \mu\text{m}$ , the power level being  $\sim 10\ \text{mW cm}^{-2}$ . When investigating the problem of efficient emission of non-ionising EM radiation by the body in order to cause ESP effects of some kind, two crucial features have to be analysed: (1) spatial resolution, and (2) penetration depth into the body (or the emission from inside the body). Although the penetration depth inside the body increases as the frequency of the radiation decreases<sup>26</sup>, if one allows the wavelength to increase beyond a certain limit the spatial resolution becomes very poor. This may not be crucial if it is just a question of emitting energy in all directions and so hopefully producing some paranormal effect in an arbitrary direction. It is critical if small objects are to be viewed by the emitted energy, such as in dowsing for a stream a metre or so wide, or clairvoyantly attempting to discern a picture a few centimetres wide on the face of a card.

We need only consider the attempt to use EM radiation for ESP purposes from the body or elsewhere at frequencies below 10 GHz. Above that frequency the penetration depth inside the

body is practically zero<sup>26,27</sup> and EM emission will be determined completely by surface temperature. Small changes of the latter by several degrees have been reported to be possible to achieve by practice. These can produce at most only a 1% change of the black-body emission from the human body and so will be useless to explain any of the ESP phenomena requiring joules of energy mentioned earlier. If we think of dowsing, telepathy or distant-viewing as produced by an active or passive radar method using the infrared emission of the body, suitably pulsed (if that were possible), the reflected or received signal would be many orders of magnitude below the known sensitivity of the skin to infrared, such as in cases of dowsing and clairvoyance cited above and others typical in the ESP literature where positive results have been claimed. Temperature changes, both of healer and patient, do occur in the faith healing situation, but do not seem to be related to any healing process<sup>1</sup>. Thus we conclude that skin emission or sensitivity cannot be relevant to ESP, and turn to frequencies below 10 GHz for which EM penetrates the human body appreciably.

For EM of radio frequencies lower than 100 MHz spatial resolution is poor due to a wavelength  $\lambda > 3\ \text{m}$ . This seems to rule out dowsing, distant-viewing and clairvoyance, due to inability to perceive objects smaller than 3 m across by such radiation. Dowers might still detect very small static magnetic fields, and underground objects can be associated with local magnetic field anomalies of the order of  $10^{-5}\ \text{G}$ . Our results<sup>1</sup> showed that dowers were unable to detect the presence of a magnet of  $\sim 200\ \text{G}$ . Therefore, it seems very unlikely that this mechanism is involved. At the lower end of the range, energy radiation is not a suitable concept, and static field ideas are more appropriate, especially in the non-black-body region below 5 kHz. Tests with healers<sup>1</sup> have indicated no changes in such levels to within millivolts of skin potential during healing sessions. Thus we can exclude this frequency range for faith healing also. Telepathy may be conjectured to occur by ELF/VLF<sup>28,29,30</sup>, especially as there is the well known Schumann resonance at 8 Hz which allows for megametre propagation with little attenuation in the Earth-ionosphere cavity. However, the coupling of the human body to the long-wavelength radiation is especially crucial (a factor (human height/ $\lambda$ )<sup>2</sup>  $\sim 10^{-14}$  entering here). Kogan's analysis<sup>30</sup> does claim that somewhat higher frequencies are just feasible. However, values for the biocurrents induced in the receiver and required for the successful telepathic transmission of information are at most  $10^{-12}\ \text{A}$  for a distance of a few metres between sender and receiver; for a 1-km separation this is reduced to  $10^{-18}\ \text{A}$ . The possible values of biocurrents produced by activity of a group of nerve cells is about  $10^{-6}\ \text{A}$ , so the induced currents are at least  $10^6$  ( $10^{12}$  for telepathy over 1 km) below that expected to noticeably bring a change of activity in a group of nerve cells. Even a single nerve cell, requiring at least  $10^{-9}\ \text{A}$  to activate it, would have too low a current induced by such telepathic signals by a factor of  $10^3$ ; as at least  $10^3$  such cells would need to be activated to 'notice' the signal, the final factor of  $10^6$  is appropriate.

The more energetic paranormal phenomena, such as movements occurring in poltergeist activity involving heavy objects, are also readily ruled out, specifically due to the energy transfer needed. For metal bending, low-frequency fields above the breakdown strength of air would be required to produce bending or breaking in metal objects. For example, for a typical strip of metal with EM frequency of 10 kHz, power absorption by the metal of 1 mW would require an electric field of  $10^6\ \text{V m}^{-1}$ .

We finally turn to the more restricted frequency range of 100 MHz to 10 GHz. There is strong evidence<sup>27</sup> against non-thermal emission of radiation by the human body or even non-thermal effects<sup>31</sup> induced in the body by very low levels of EM radiation. The power level emitted by the human body at microwave frequencies of 1–5 GHz is of the order of  $10^{-14}\ \text{W}$ . Therefore we can immediately discard the EM explanation for the more highly energetic phenomena that is materialisation, poltergeist, metal-bending and PK (translational motion of

objects). Clearly these are too low in energy by a factor of  $10^{12}$  at least and up to  $10^{20}$  for materialisation. One of the less energetic phenomena, psychic healing, would be also down by a factor of  $10^{11}$ . It only remains to be seen how EM stands as regards the other less energetic phenomena, such as dowsing, telepathy, clairvoyance and distant-viewing. Two types of mechanisms can be envisaged for the less energetic phenomena: an active or a passive radar-like type.

Consider first site-dowsing. If we think of a dowser being able to detect underground water by means of an active radar-like mechanism, we see that radiation in the range 1–5 GHz at a power level of  $10^{-14}$  W would be attenuated when penetrating through the soil, its skin depth being of a few cm. If a dowser used a passive radar-like mechanism, this would involve him sensing a cold spot (the underground stream) from an otherwise warmer environment at a depth, say, of 20 m. Our tests<sup>1</sup> on human sensitivity to low-level (1–5 mW) EM radiation in this frequency range indicate a lack of sensitivity by a factor of  $10^{10}$ . The problems are even more difficult for map-dowsing because of the distance sometimes involved. The active radar mechanism can be ruled out, as the propagation distance of EM radiation of frequencies of 1–5 GHz is  $<100$  km and dowsers have claimed map-dowsing successes up to a few thousand kilometres. The upper limit for round-the-world propagation of an EM signal is 70 MHz ( $\lambda \geq 40$  m)<sup>32</sup>, and even then at power levels at least  $10^{14}$  times greater than those from humans. There is also the problem of spatial resolution, as  $\lambda \geq 40$  m and it could never account for the size of objects perceived (a few centimetres in some cases).

The cases of clairvoyance (direct or remote) and distant-viewing<sup>33</sup> also involve the problem of the size of the object perceived as compared with the wavelength that could be used by the subject ( $\lambda \sim 6$ –300 cm). The minimum size  $d_{\min}$  of an object observable at a distance  $R$  from an aerial of the size of the human body using radiation limited to a maximum frequency of 3 GHz for deep body penetration, satisfies  $d_{\min} \geq R/40$ , from standard diffraction theory. If  $R \sim 1$  m,  $d_{\min} \geq 2.5$  cm, contradicting the supposed ability in ref. 34 to read symbols down to 1/30 cm in size on a card a metre away. If  $R \sim 4$  km,  $d_{\min} \geq 100$  m, contradicting the distant-viewing abilities reported in the SRI tests<sup>33</sup> of observations of objects only 1 cm across.

Telepathy involves one subject (sender) transmitting encoded information to another. The receiver must then sense the incoming information, decode it and produce an output that can be compared with the original one sent to him. Here again, it is in the frequency range 1–5 GHz that this transmission would be most efficient. However, if we assume that the sender is using black-body EM radiation he is emitting in that frequency range, (necessarily above 10 kHz<sup>27</sup>), the power level of the signal would be so low (by a factor of  $10^5$  for people 1 km apart) that it could never be sensed by the receiver. Our experiments have confirmed this by showing that human sensitivity is very poor at these frequencies<sup>1</sup>.

We therefore conclude that neither EM nor any other scientific theory can explain any of the above mentioned ESP phenomena.

In particular there is no reason to support the common claim that there still may be some scientific explanation which has as yet been undiscovered. The successful reductionist approach of science rules out such a possibility except by utilisation of energies impossible to be available to the human body by a factor of billions.

We can only conclude that the existence of any of the psychic phenomena we have considered is very doubtful.

E.B. thanks the Sedwood Trust for financial support. We also thank Dr P. C. W. Davies for helpful discussions on advanced potentials.

## A pachycephalosaurid dinosaur from Madagascar and a Laurasia–Gondwanaland connection in the Cretaceous

THE discovery of a pachycephalosaurid dinosaur in the Upper Cretaceous of Madagascar is reported here. This finding casts new light on the existence of a land connection (or several such connections) between Laurasia and Gondwanaland sometime in the Lower or Mid-Cretaceous. Hitherto this family of dome-headed ornithischians had only been known from the Northern Hemisphere: from the Lower Cretaceous of England<sup>1</sup> and the Upper Cretaceous of North America<sup>2</sup> and East Asia<sup>3</sup>.

Previously the evidence for a faunal connection between Laurasia and Gondwanaland during the Cretaceous was slight<sup>4</sup>. The frequently cited cosmopolitan distribution of the sauropod dinosaur *Titanosaurus* is based on very incomplete and often plainly non-diagnostic material and it is not improbable that several related genera are involved. The discovery of a dromaeosaurid in the Upper Cretaceous of Brazil has been reported<sup>4</sup> but the lack of detailed information or illustrations makes evaluation of this record impossible. Hadrosaurine hadrosaurs are now known from several specimens from the Upper Cretaceous of Argentina<sup>5,6</sup>; they previously represented the only, and more substantial, evidence for faunal exchange between Laurasia and Gondwanaland sometime in the Cretaceous. Fragmentary tyrannosaurid remains have been described from the Upper Cretaceous of India<sup>7</sup> and South America<sup>8,9</sup>. All other records of Laurasian dinosaur families from the Southern Hemisphere, which evolved solely within the Cretaceous period, are based on extremely fragmentary material which either lacks the diagnostic characters of the respective group or has been incorrectly determined<sup>7</sup>.

The supposed presence of a ratite bird, a member of a group otherwise restricted to the Southern Hemisphere, in the Upper Cretaceous of Mongolia is very doubtful; this form has been described on the basis of two badly crushed and incomplete

Fig. 1 *Majungatholus atopus*, new genus and species. MNHN.MAJ 4. Partial skull; stereo-photographs in dorsal (a) and lateral (b) view. Scale bar, 3 cm.

skulls<sup>10</sup>. It is quite unlike any known palaeognathous bird<sup>10</sup> and in our opinion even its avian nature is not well established<sup>9</sup>.

The new find of a pachycephalosaurid comes from the Upper Cretaceous (probably Campanian) of the Majunga District in northwestern Madagascar. It was recently discovered by P.T. The specimen was collected at the beginning of this century; its true nature was not recognised at that time. The deposits in the Majunga region have yielded a rather diversified fauna of vertebrates<sup>9,11,12</sup>, including a sauropod, a theropod and two teeth first referred to *Stegosaurus*<sup>13</sup> but probably referable to some other group of ornithischians<sup>9</sup>.

Class: Reptilia

Order: Ornithischia

Suborder: Ornithopoda

Family: Pachycephalosauridae

*Majungatholus*, new genus.

Type species: *Majungatholus atopus*, new species.

**Derivatio nominis:** The generic name is derived from the name of the region where the specimen was found and the Latin *tholus*, 'dome'.

**Diagnosis:** A single dome-like thickening of the frontal region; frontal dome thick, with highly irregular, rugose dorsal surface. Parietal without significant thickening, participating in a well developed parieto-squamosal shelf. Very large supratemporal fenestrae. Olfactory portion of the braincase long; olfactory lobes ventrally enclosed by bone.

*Majungatholus atopus*, new species.

**Holotype:** Skull roof consisting of frontals and incomplete parietals and anterior part of the braincase (Fig. 1). Muséum National d'Histoire Naturelle, Paris, MNHN.MAJ 4 (formerly in the collections of the Ecole des Mines, Paris).

**Locality and horizon:** 'Grès de Maevarano'<sup>9,12</sup>, Upper Cretaceous (probably Campanian), Majunga District, north-western Madagascar.

**Derivatio nominis:** The specific epithet is derived from the Greek *atopos*, 'strange' (or, in its original derivation, 'out of place'—a perhaps more appropriate meaning in the present context).

**Diagnosis:** As for the genus.

The specimen, a detailed anatomical description of which will be presented elsewhere<sup>9</sup>, evidently represents a dome-headed dinosaur referable to the Pachycephalosauridae. Like other pachycephalosaurids, it differs from the Ankylosauria in showing very long olfactory stalks and thickening of the cranial roof bones by upgrowth of the bones rather than by fusion of dermal ectopic elements<sup>14</sup>. Furthermore, in ankylosaurs the upper temporal fenestrae are always closed<sup>15</sup>.

*Majungatholus* represents a distinctive type of the dome-headed ornithischians; its single frontal dome and its very large upper temporal fenestrae are unique features. The earliest known pachycephalosaurid, *Yaverlandia bitholus*, from the Lower Cretaceous (Wealden) of the Isle of Wight<sup>1</sup>, shows some resemblance in having large supratemporal fenestrae and thickening restricted to the frontal region; it differs, however, in having a small dome on each frontal and in being much smaller. The only Upper Cretaceous pachycephalosaurid species showing a certain similarity is a flat-headed form referred to *Stegoceras* from the Campanian of Alberta, Canada<sup>1</sup>. In this species the supratemporal fenestrae are large and a parieto-squamosal shelf is well developed; the frontals, however, are but slightly thickened and the species is smaller than *Majungatholus atopus*. A peculiar feature only present in *Majungatholus* and the two Laurasian species mentioned above is a median circular depression on the postero-dorsal surface of the frontals.

*Majungatholus* can be derived from a *Yaverlandia*-like form and probably represents a lineage evolving in geographical separation from Northern Hemisphere pachycephalosaurids.

The presence of a pachycephalosaurid in Madagascar and of other 'Laurasian' dinosaur families in the Southern Hemisphere during the Late Cretaceous can be explained in two different ways. First, dispersal from Laurasia could be assumed as all these families have their greatest diversity and most primitive species in the Northern Hemisphere. The Tethyan sea belt separated the two super-continent<sup>16</sup> during the Cretaceous but it was at least in part a fairly shallow epicontinental sea and passage routes may have become available on several occasions. The exact locations of some of these connections may never be known as many potential areas have subsequently been affected by Cretaceous and Tertiary orogeneses. Cox<sup>4</sup> has suggested the existence of a filter route in the Central American or Caribbean region to account for the presence of a hadrosaur in Argentina. But it can also be argued that the existence of similar dinosaurs in both hemispheres is the result of vicariance events (the breakup of Pangea). The evidence presently available does not permit a choice between the two hypotheses. It is clear that faunal exchange by land connections between Laurasia and Gondwanaland was possible at least during the first half of the Cretaceous, possibly even at a later date.

The photographs for Fig. 1 were prepared by A. H. Coleman of Harvard University.

## Growth of host root establishes contact with parasitic angiosperm *Boschniakia hookeri*

MEMBERS of the family Orobanchaceae are root parasites attached underground to suitable hosts. In some cases attachment is effected by special mechanisms of the parasite. For example, the mature seed of *Orobanche*, stimulated chemotropically by diffusion of compounds from the host, germinates and its extending radicle establishes contact with the host<sup>1,2</sup>. We report here a previously unknown mechanism in *Boschniakia hookeri*, a perennial parasite found only on the roots of certain members of the Ericaceae in a narrow westerly distribution on the North American continent. We found that the connection of the parasite to the host is due ultimately to the behaviour of the host root, which grows through the testa of the parasite's seed into contact with the embryo.

We studied a population of *B. hookeri* growing in Kitsap County, Washington. Field observations showed that dispersal of the seeds depends in part on the properties of the seeds themselves, and in part on environmental factors. The mature seeds, as they are exposed in the ripe capsule, are relatively large ( $1.8 \pm 0.2$  mm), non-wettable, and of low specific gravity ( $0.2-0.25$ ). These properties result from the structure of the testa, a light, dry, honeycomb-like sheath surrounding the small embryo (about  $0.4 \times 0.3$  mm). Thus the seeds are easily displaced and chance movements (rain drops, animal contact) release them

**Fig. 1** Duff taken from below *Gaultheria shallon*. Many seeds of *Boschniakia hookeri* are present, as well as young roots of *Gaultheria*. The characteristic outer layer of deeply pitted cells of the testa (seed coat) makes it easy to recognise the *Boschniakia* seeds.

**Fig. 2** Branched roots of *Gaultheria shallon* with the root-tips growing through the outer testa cells towards the embryo. Material identical with seeds in Fig. 1.

from the capsule. Further dispersal is probably mainly through natural pores in the soil, or through tunnels made by small mammals (such as moles and mice). Occasional underground hoarding of seeds by mammals may also be a factor, although of secondary importance. Apparently the site of germination and the resulting tuber is determined merely by where seed and host root meet. Some tubers were found just beneath the surface, while in other cases tubers were as much as 25 cm below the surface—a depth of 10–15 cm was most common.

The embryo does not contain specialised organs<sup>3</sup> and apparently does not take an active part in the contact with the root. Connection is established by the young root-tip of the host, growing into and through the large outer cells of the testa (Figs 1, 2) until it presses against the embryo of the parasite. Later, the tissues of the parasitic embryo and the host merge. Cell division of the seed results in the formation of a tuber, in which vascular and meristematic tissues differentiate. This process can occur within 2–4 months from the time when the root and seed first come into contact. Apparently germination is not strictly dependent on the season, for young tubers are found in a continuous series of sizes, with a very close correlation between their dimensions and the diameter of the host roots.

The attraction between host root and parasite seems highly effective, although unexplained. For example, in germination experiments up to 75% of seeds placed on the roots of young *Arctostaphylos uva-ursi* were later found with the host roots growing into them. It is possible that the host roots are attracted by exudates from the embryo or testa. But as host root-tips can penetrate non-living organic particles (such as fragments of tree bark) and inorganic particles in the soil (such as artificially introduced Perlite, a heat-expanded volcanic glass), it may be

that the physical characteristics of the outer cells of the parasite's testa alone result in the contact-seeking growth of the host root.

## Human blood platelet adhesion to artery subendothelium is mediated by factor VIII–Von Willebrand factor bound to the subendothelium

ONE of the early events in the haemostatic process is the adherence of blood platelets to collagen of the subendothelium. Subsequent platelet-to-platelet adhesion then leads to the formation of a haemostatic plug. The role of a plasma factor in this process was recognised after the discovery<sup>1,2</sup> that the prolonged bleeding time of patients with Von Willebrand disease could be corrected by transfusion of plasma or cryoprecipitate. This plasma factor, then named Von Willebrand factor, was later identified as factor VIII (anti-haemophilic

factor A (ref. 3)). The current concept is that Von Willebrand factor and factor VIII are present in a complex, which can be dissociated in certain conditions. Despite this progress, little is yet known about the role of the factor VIII–Von Willebrand factor complex (factor VIII–VWF) in the haemostatic plug formation. Tschopp *et al.* showed that the Von Willebrand factor was required for normal adhesion of platelets to rabbit subendothelium in a perfusion chamber using blood from patients with Von Willebrand disease<sup>4</sup>. The role of factor VIII–VWF in platelet adhesion is also important for the development of atherosclerosis. In this process, adherence of platelets is followed by degranulation and concomitant secretion of factors causing intimal migration and proliferation of smooth muscle cells<sup>5,6</sup>. Defective adherence of platelets was shown to protect against experimental atherosclerosis<sup>7,8</sup>. We present here evidence that factor VIII–VWF binds to subendothelium of human arteries and that subendothelium-bound factor VIII–VWF mediates the platelet adhesion.

A perfusion chamber as developed by Baumgartner<sup>9</sup> was used to study the effect of factor VIII–VWF on platelet adhesion to subendothelium, but using components of human origin only. Blood from healthy donors was anticoagulated with citrate. Platelets were washed in Krebs–Ringer solution, labelled<sup>10</sup> with <sup>51</sup>CrO<sub>4</sub> and incubated with aspirin to prevent platelet–platelet interaction<sup>11</sup> (for details see Fig. 1). Factor VIII–VWF was isolated from human cryoprecipitate<sup>12</sup> and labelled with <sup>125</sup>I by the lactoperoxidase method<sup>13</sup>. Subendothelium of human postmortem renal arteries after the first bifurcation was used; arteries with macroscopically observable atherosclerotic lesions were discarded. Perfusions were carried out at a shear rate comparable to that in arteries<sup>14</sup>.

In the first set of experiments the specificity of the effect of factor VIII–VWF on the adhesion of <sup>51</sup>Cr-platelets was studied. After perfusion for 5 min at 37 °C with normal plasma containing red cells (haematocrit 40%) and <sup>51</sup>Cr-platelets ( $2.5 \times 10^5$  per

**Fig. 1** Light microscopical picture ( $\times 1,100$ ) of human subendothelium after perfusion with aspirin-treated platelets. No platelet interaction could be detected, only a monolayer of platelets covering the subendothelium. All arteries used had subendothelial fibrosis. Fixation, embedding, cutting and staining was after Baumgartner<sup>15</sup>. The arteries were obtained from autopsies usually 12 h after death. They were exposed to air for a few minutes to remove endothelial cells completely, and the lumen was wiped with a bud probe. Finally, the lumen was rinsed with 0.2 M Tris buffer (pH 7.4). On light microscopical examination no endothelial cells could be detected. The reconstituted blood used for the perfusions was anticoagulated with 19 mmol citrate (plasma concentration). Platelet-rich plasma (PRP) was obtained from whole blood by centrifugation (10 min at 190g, 20 °C). To one volume of PRP one volume of a Krebs–Ringer solution (4 mM KCl, 107 mM NaCl, 20 mM NaHCO<sub>3</sub> and 2 mM Na<sub>2</sub>SO<sub>4</sub>) containing 19 mM citrate and 0.5% glucose (pH 5.0) was added which gave a final pH of 6.1. Platelets were spun down (10 min, 500g, 20 °C) and resuspended in 2 ml Krebs–Ringer solution (with citrate and glucose, pH 6.1) four times. The second time 1  $\mu$ Ci CrO<sub>4</sub> per ml was added to the resuspended platelets (about  $10^6$  per  $\mu$ l) and centrifugation was carried out after 20 min at 20 °C. The third time, 10  $\mu$ M aspirin was added for 15 min at 37 °C. After the fourth washing over 97% of the <sup>51</sup>CrO<sub>4</sub> was intracellular. Platelet poor plasma (PPP) was obtained from PRP by centrifugation (15 min, 3,000g, 4 °C). Plasma contamination of the red cells was avoided by three washings in saline containing 2% glucose. The labelled platelets, PPP and the red cells were reconstituted to give  $2.5 \times 10^5$  platelets per  $\mu$ l plasma and a red cell concentration of approximately 40%. The pH was adjusted to 7.3. The perfusates were incubated for 5 min at 37 °C before the perfusions were carried out. A peristaltic tube pump (Verder) was used for the perfusions. The average flow rate was 135 ml min<sup>-1</sup> and the average shear rate was calculated to 805 s<sup>-1</sup>. All perfusions were carried out for 5 min at 37 °C. Immediately after perfusion the system was rinsed with 40 ml 0.2 M Tris buffer (pH 7.4). A segment of approximately 2.5 mm was cut from both ends of the artery. It was calculated that a 2.5-mm broad area of turbulence would occur where the flow met the edge of the vessel wall<sup>16</sup>. The remaining part ( $\sim 0.5$  cm<sup>2</sup>) was used for registration of <sup>51</sup>Cr (Trigamma 600, Baird Atomic).

**Table 1** Platelet adherence to subendothelium in media with and without factor VIII-VWF

	Platelet no. ( $\times 10^5$ ) per $\text{cm}^2$ subendothelium (mean $\pm$ s.d.)	
	Without addition of factor VIII-VWF	Addition of 1 U factor VIII-VWF per ml
Normal plasma	—	71.5 $\pm$ 11.0 (7)
Haemophilia A plasma	—	67.2 $\pm$ 5.8 (5)
Von Willebrand plasma*	28.8 $\pm$ 8.2 (11)	73.3 $\pm$ 8.7 (6)
Plasma after cryoprecipitation†	24.5 $\pm$ 7.6 (6)	70.2 $\pm$ 5.3 (5)

$\mu\text{l}$  plasma),  $70 \times 10^5$  platelets per  $\text{cm}^2$  subendothelium were detected. When normal plasma was substituted by plasma from patients with Von Willebrand disease or by supernatant plasma after cryoprecipitation, the platelet adhesion was markedly decreased. A similar decrease was found on substitution of normal plasma by solutions of human albumin or dextran, which indicated that no proteins other than factor VIII-VWF play a part in the platelet adhesion. Indeed, addition of factor VIII-VWF to these plasma substitutes corrected the platelet adhesion to the same level as obtained with normal plasma (Table 1). This normalisation was reached in a relatively small range (0.5–0.8 U per ml of factor VIII-VWF as measured in the ristocetin cofactor assay<sup>17</sup>).

The mechanism by which factor VIII-VWF promotes the adhesion of platelets to the subendothelium was studied in the following way. First, perfusions (5 min, 37 °C) were carried out using solutions of human albumin and factor VIII-VWF (1 U  $\text{ml}^{-1}$  including 10%  $^{125}\text{I}$ -factor VIII-VWF). These experiments indicated a binding of  $10^{-3}$  U factor VIII-VWF per  $\text{cm}^2$  subendothelium. Then, double-perfusion experiments were carried out to study the influence of bound factor VIII-VWF on the platelet adhesion. Subendothelium was perfused with human albumin solutions containing various amounts of  $^{125}\text{I}$ -factor VIII-VWF, followed by a second perfusion with red cells and  $^{51}\text{Cr}$ -platelets in albumin solutions without factor VIII-VWF. Figure 2 shows the relationship between the concentration of factor VIII-VWF and the binding of this protein to the subendothelium (A) and the dependence of the platelet adhesion on the amount of factor VIII-VWF bound (B). A nearly normal adhesion was obtained after binding of about  $10^{-3}$  U factor VIII-VWF per  $\text{cm}^2$  subendothelium ( $4 \times 10^9$  molecules per  $\text{cm}^2$ ). Removal of factor VIII-VWF from the subendothelium during the second perfusion could not be detected. It should be mentioned that even complete desorption would yield a negligible concentration of factor VIII-VWF in the second perfusate.

From these experiments, carried out with human components in conditions which mimic the *in vivo* situation after vessel wall injury, we conclude (1) that for normal adhesion factor VIII-VWF is the only plasma protein necessary, and (2) that factor VIII-VWF bound to subendothelium is a highly effective inducer of platelet adhesion.

The results strongly suggest that binding of factor VIII-VWF to subendothelium is an important step in the first phase of the haemostatic plug formation. This is supported by ultrastructural studies of haemostatic plugs in Von Willebrand patients<sup>18,19</sup> showing a disturbed adherence of platelets to the vessel lips and the presence of free platelet aggregates in the wounds. The effect of factor VIII-VWF on platelet adhesion may also be important for the development of atherosclerosis, as was concluded by Fuster *et al.*<sup>8</sup>, who showed that pigs with severe Von Willebrand disease are much less susceptible to atherosclerosis than control pigs.

Furthermore, the present results are interesting in view of the synthesis of factor VIII-VWF-related antigen (with Von

**Fig. 2** Factor VIII-VWF accumulation and the subsequent platelet adhesion on human subendothelium in a double-perfusion experiment. A, Factor VIII-VWF bound to the subendothelium in the first perfusion (○) with different factor VIII-VWF concentrations. B, Number of platelets adhered to the subendothelium in the second perfusion (●), with the corresponding amount of pre-bound factor VIII-VWF. Dashed curves are power curve fits according to the formula  $y = ax^b + c$ , where in A:  $a = 1.23$ ,  $b = 0.70$ ,  $c = 0.0$  and the correlation coefficient  $r = 0.85$ , and in B:  $a = 26.0$ ,  $b = 0.86$ ,  $c = 26.7$  and  $r = 0.84$ . In the first perfusion a Krebs-Ringer solution containing 19 mM citrate, 2.4 mM  $\text{CaCl}_2$ , 0.5% glucose and 4% human albumin (recrystallised, Sigma A 9511) with different concentrations of purified factor VIII-VWF was perfused for 5 min, at 37 °C. 10% of the purified factor VIII-VWF was labelled with  $^{125}\text{I}$ . After the first perfusion, the system was rinsed with 135 ml 0.2 M Tris buffer (pH 7.4). The second perfusion (5 min, 37 °C) was then started immediately. This perfusate contained the Krebs-Ringer solution as used in the first perfusion but without factor VIII-VWF. Platelet and red cell concentrations were similar to the concentrations, as indicated in Fig. 1 legend. After the second perfusion, the system was rinsed with 40 ml 0.2 M Tris buffer (pH 7.4). The middle part of the artery was cut from the rod and used for registration of  $^{51}\text{Cr}$  and  $^{125}\text{I}$ .

Willebrand activity but without coagulant activity) in the endothelial cells<sup>20</sup>. On vessel wall injury, this antigen may be bound to the subendothelium and subsequently mediate the adhesion of platelets. A local haemostatic effect of factor VIII-VWF-related antigen present in the vessel wall has been suggested by Bloom *et al.*<sup>21</sup> on the basis of immunohistochemical studies of the intima and by Holmberg *et al.*<sup>22</sup> who reported the absence of this antigen in the vessel wall of severely affected Von Willebrand patients.

We thank Dr H. R. Baumgartner (Roche) for his advice concerning the perfusion procedure and Dr L. van Gorp and H. Westendorp (St Anthonius Hospital, Utrecht) for the supply of renal arteries. Financial support was obtained from the Netherlands Heart Foundation (grant no. 76090).

## Calcium conductance of acetylcholine-induced endplate channels

SEVERAL lines of evidence indicate that an influx of  $\text{Ca}^{2+}$  ions accompanies transmitter activation of the postsynaptic membrane at the neuromuscular junction<sup>1–5</sup>. We report here that we have now investigated the elementary characteristics of the  $\text{Ca}^{2+}$  current by bathing muscles in  $\text{CaCl}_2$  solutions containing no  $\text{Na}^+$  ions, so that  $\text{Ca}^{2+}$  is the only ion available to carry any appreciable inward current<sup>1,3,6,7</sup>. The single channel current ( $i$ ) and mean lifetime ( $\tau$ ) of the postsynaptic channels were then determined by the technique of noise analysis<sup>8,9</sup>. It was found that  $\tau$  in the  $\text{Ca}^{2+}$  solution was shorter than in normal Ringer, but that the voltage dependence of  $\tau$  was unchanged. The elementary current showed a non-linear voltage dependence, unlike the linear dependence in normal solution<sup>8</sup>.

Experiments were carried out on the frog (*Rana temporaria*) sartorius muscle, at a temperature of 5–6 °C. The muscle was strongly stretched to reduce contraction and its associated artefacts. The normal bathing solution contained (in mM): NaCl, 120; KCl, 2;  $\text{CaCl}_2$ , 1.8; HEPES, 4 (pH 7.2). Calcium solutions contained:  $\text{CaCl}_2$ , 82 or 160; KCl, 2; HEPES, 4 (pH 7.2): care was taken to avoid contamination with  $\text{Na}^+$ . A standard two-point voltage clamp was used at the endplates, and a third external micropipette filled with 2 M acetylcholine (ACh) was used to apply ACh ionophoretically to the endplate. A fast

**Fig. 1** Membrane potential dependence of the ACh-induced single channel lifetime,  $\tau$ , measured from muscles bathed in normal Ringer solution (●) and in isotonic or hypertonic  $\text{Ca}^{2+}$  solutions (○). No differences were seen in  $\tau$  between isotonic and hypertonic  $\text{Ca}^{2+}$  solutions, and the results shown are pooled data from both. Lines were fitted by eye, and error bars give  $\pm 1$  s.d. Five endplates were examined in Ringer solution, and seven in  $\text{CaCl}_2$  solutions. Values were obtained during steady ionophoretic application of ACh to voltage-clamped endplates, by fitting the membrane current fluctuation spectra to a lorentzian curve. Background spectra were subtracted before fitting.  $\tau$  was calculated from the half power frequency  $f_c$  of the spectra as  $\tau = 1/(2\pi f_c)$ . About 15 noise segments of 512 points were obtained at each potential, at a digitisation rate of 500 or 1,000 Hz, and were used to compute an average spectrum.

Fourier transform method was used to analyse the frequency components of the current fluctuations during steady ACh application, and  $i$  and  $\tau$  were determined as previously described<sup>8,9</sup>.

Records were usually obtained from several fibres in normal Ringer solution, and then from the same, and additional fibres, after changing to  $\text{Ca}^{2+}$  solution. Resting membrane potentials were higher in isotonic and hypertonic  $\text{Ca}^{2+}$  solutions (mean values: normal Ringer  $85.1 \pm 5.8$  mV,  $\text{Ca}^{2+}$  solution  $103 \pm 7.2$  mV: all deviations are  $\pm 1$  s.d. unless otherwise stated), and the input resistance of the fibres was increased (normal Ringer  $\sim 350$  k $\Omega$ ;  $\text{Ca}^{2+}$  solution  $1.32 \pm 0.38$  M $\Omega$ ). Pipettes with large tip diameters were used to reduce background noise, and the values given above may be artificially low because of fibre damage during penetration. The frequency of miniature endplate potentials was elevated after changing to  $\text{Ca}^{2+}$  solution, but fell to nearly zero after 2–3 h, when ACh noise recordings could be made. Miniature endplate currents (m.e.p.cs) were reduced in duration and size in  $\text{Ca}^{2+}$  solution (see also ref. 3), mean amplitudes at  $-130$  mV being  $2.86 \pm 0.39$  nA in normal Ringer, and  $0.97 \pm 0.37$  nA in  $\text{Ca}^{2+}$  solution.

In normal Ringer, ionophoretic application of large doses of ACh to the endplate caused local contractions, and these became much larger in isotonic  $\text{Ca}^{2+}$  solution. For example, a barely visible contraction, involving two sarcomeres, was seen with a synaptic charge flux of about 1 nC. Because of this difficulty in avoiding movement artefacts, some experiments were carried out in hypertonic  $\text{Ca}^{2+}$  solution (160 mM  $\text{CaCl}_2$ ), which helped to reduce contraction. To guard against the possibility that part of the synaptic current was carried by an influx of  $\text{Cl}^-$  ions<sup>7</sup>, recordings were made from two fibres in a bathing solution of 82 mM Ca-cyclamate. M.e.p.cs were recorded in this solution, with the same amplitudes as in 82 mM  $\text{CaCl}_2$  solution, and there was little difference in reversal potential. Also  $\text{K}^+$  ion influx made no appreciable contribution to the synaptic current, as no significant changes in equilibrium potential or single channel currents were seen in fibres bathed in a solution containing only 160 mM  $\text{CaCl}_2$ .

A variety of divalent cations in addition to  $\text{Ca}^{2+}$  are able to carry a synaptic current. We have recorded m.e.p.cs and ACh-induced currents from fibres bathed in isotonic solutions of  $\text{MgCl}_2$ ,  $\text{MnCl}_2$ ,  $\text{SrCl}_2$  and  $\text{CoCl}_2$  (all solutions also contained 2 mM KCl and 4 mM HEPES). This contrasts with the

behaviour in several other systems, where  $Mg^{2+}$ ,  $Mn^{2+}$  and  $Co^{2+}$  are known to block  $Ca^{2+}$  fluxes<sup>10-13</sup>. The drug D600 has also been shown to block  $Ca^{2+}$  fluxes in a variety of preparations<sup>11-13</sup>. We found that at a concentration of  $200 \mu g ml^{-1}$  D600 decreased the frequency of m.e.p.s in isotonic  $Ca^{2+}$ , and did not abolish the ACh sensitivity of the muscle membrane. However, with ionophoretic ACh application only brief transient responses could be recorded, and a period of a few minutes was required for recovery of the response to a second pulse. This effect of D600, which was also present in normal Ringer, may be attributable to a blocking of open channels, or to an increase in desensitisation.

Figure 1 shows the voltage dependence of mean lifetime ( $\tau$ ) of ACh-induced channels in  $Ca^{2+}$  solution, plotted on semi-logarithmic coordinates. The data are fitted well by a straight line, indicating that  $\tau$  increases exponentially with membrane hyperpolarisation. The voltage constant (potential shift to give an  $e$ -fold change in  $\tau$ ) was 62 mV.  $\tau$  increases exponentially with hyperpolarisation in normal Ringer<sup>8</sup>, and the  $Ca^{2+}$  data closely parallel a line drawn through control measurements in normal Ringer, although shifted in a hyperpolarised direction by about 46 mV. The shortening of  $\tau$  in  $Ca^{2+}$  solution is surprising, as an increase in  $Ca^{2+}$  concentration from 1 to 10 mM has been reported to slow the decay phase of m.e.p.s<sup>14</sup>. However, we have been unable to confirm these results, and found that this increase in  $Ca^{2+}$  concentration produced in some experiments a shortening of m.e.p.c. decay, and in others no detectable change.

Figure 2 shows the voltage dependence of the elementary current, derived from noise analysis, in hypertonic  $Ca^{2+}$  solution. The relationship is not linear throughout, indicating that the elementary conductance ( $\gamma$ ) varies with membrane potential. Closely similar behaviour was seen in experiments using isotonic  $Ca^{2+}$  solution. This is unlike the situation in normal Ringer, where  $\gamma$  is independent of potential<sup>8</sup>, and in our experiments had a value of  $29.3 \pm 2.7$  pS (s.e.m.). In hypertonic  $Ca^{2+}$  solution the voltage dependence of  $i$  was approximately linear at potentials more hyperpolarised than -110 mV, and the slope of this segment gave a value for  $\gamma$  of 6.25 pS. Noise measurements at potentials between equilibrium and -100 mV were very difficult to obtain, but an average value for  $\gamma$  of  $\sim 2.5$  pS was estimated for this segment.

Our results confirm previous observations<sup>1-5</sup> showing that activation of the postsynaptic membrane with ACh causes an increase in permeability to  $Ca^{2+}$  ions, and further indicate that  $Mg^{2+}$ ,  $Mn^{2+}$ ,  $Sr^{2+}$  and  $Co^{2+}$  ions are also able to cross the channels induced by ACh. However, the conductances for these ions are small, and at -90 mV, for example, the elementary conductances in both isotonic  $MgCl_2$  and  $CaCl_2$  solutions are about 10 times less than in normal Ringer.

Divalent ions might cross the endplate membrane (1) nonspecifically through the 'ordinary' channels normally used

by  $Na^+$  and  $K^+$ , or (2) through a separate  $Ca^{2+}$ -specific channel. The apparently identical voltage dependence of  $i$  for  $Ca^{2+}$  and  $Na^+$  currents, together with the failure of  $Mg^{2+}$ ,  $Mn^{2+}$ ,  $Co^{2+}$  and D600 to block the m.e.p.s, favour (1), but do not entirely exclude (2). The reason for the differences in conductance properties in Na- or Ca-Ringer is not clear, and the non-linear dependence of the elementary  $Ca^{2+}$  current on membrane potential is not predicted by the Goldman-Hodgkin-Katz model of ion permeation<sup>15-18</sup>. However, differences also exist between various divalent ions themselves, and we find that, unlike  $Ca^{2+}$ , the elementary  $Mg^{2+}$  current has a linear voltage dependence over the range examined (-50 to -130 mV).

The decrease in channel lifetime in  $Ca^{2+}$  solutions is in the opposite direction to that expected from the effect of  $Ca^{2+}$  ions in screening negative surface charges on the muscle membrane<sup>14</sup>, and suggests that  $Ca^{2+}$  ions have an additional effect on the channel. It may be that in addition to direct effects of various ions on the receptors and their environment, the lifetime of transmitter-induced channels is influenced by the nature of the ions which permeate them<sup>19</sup>.

We thank Sir Bernard Katz for helpful discussion, and Abbot laboratories for D600.

**Fig. 2** Membrane potential dependence of the single channel current  $i$ , measured from fibres bathed in 160 mM  $CaCl_2$  solution. Lines were fitted by eye. Points shown with error bars are means from five fibres, and bars are  $\pm 1$  s.e.m. Points at -90 and -70 mV are measurements from single fibres. The equilibrium potential (●) was measured from the reversal potential of the ACh response in seven fibres, and was -44.4 mV (s.d.  $\pm 1.1$  mV). Elementary currents were calculated from the total spectrum variance, after subtraction of background variance. The alternative technique of computing  $i$  from the zero frequency asymptote of the spectra gave values in good agreement.

## Anti-HLA-A,B,C monoclonal antibodies with no alloantigenic specificity in humans define polymorphisms in other primate species

THE study of evolutionary relationships by immunological comparison of homologous proteins from different species has been limited by the complexity and variability of conventional heteroantisera<sup>1</sup>. These problems can be avoided by using selected panels of monoclonal antibodies, specific for single antigenic determinants, which would enable detailed immunochemical descriptions of homologous proteins to be made<sup>2</sup>. The human HLA-A,B,C antigens and their homologues provide a particularly interesting system for this type of analysis<sup>3</sup>. Although they are extraordinarily polymorphic within species, many features of their structure, including association with  $\beta_2$ -microglobulin, have been highly conserved during evolution<sup>4-6</sup>. A preliminary survey showed that monoclonal antibodies with specificity for the HLA-A,B,C- $\beta_2$ -microglobulin complex reacted with primate species but not with non-primates<sup>7</sup>. We have therefore

**Fig. 1** Indirect trace binding of W6/32 antibody to lymphocytes of different primate species. The assay was basically as described in ref. 14. Peripheral blood lymphocytes ( $5 \times 10^5$ ) in a volume of 50  $\mu$ l were incubated with 50  $\mu$ l of a 1/100 dilution of ascites fluid from mice carrying the W6/32 hybrid cell as a tumour, for 1 h at 4°C. After three washes the cells were incubated with  $2 \times 10^6$  c.p.m. of  $^{125}$ I-labelled rabbit (Fab')<sub>2</sub> anti-mouse IgG for 1 h at 4°C, washed four times and counted for radioactivity.

concentrated on comparing primate species with a panel of anti-A,B,C monoclonal antibodies. We report here the finding that two different anti-HLA-A,B,C monoclonal antibodies with no demonstrable polymorphic specificity in humans define polymorphisms in owl and spider monkeys, thus demonstrating the potential of these reagents for fine structure antigenic mapping.

Results obtained from a limited number of species indicated that the anti-HLA-A,B,C monoclonal antibody W6/32 reacted with apes and Old World monkeys whereas the anti- $\beta_2$ -microglobulin monoclonal antibody BBM1 only reacted with the higher apes, chimpanzee and gorilla<sup>7,8</sup>. The indirect binding of W6/32 to peripheral lymphocytes from individual animals of 19 primate species is shown in Fig. 1. Positive reactions were found with all species of Old World monkeys and the only ape (gibbon) tested. All New World species, with the exception of the owl monkey, were negative. The BBM1 antibody, as expected (ref. 7, and data not shown), was negative against all non-human species tested.

To confirm the presence of the W6/32 antigenic determinant on owl monkey lymphocytes four animals were individually tested. Three gave negative reactions and the single animal tested in the original screen was still positive. Subsequent typing of 40 owl monkeys showed 11 positive and 29 negative. When lymphocytes from W6/32 positive and negative animals were assessed for their capacity to bind W6/32 antibody (Fig. 2), positive animals gave titration curves indistinguishable from human and rhesus lymphocytes, in contrast to negative animals, which gave no significant binding at any cell number and were indistinguishable from spider monkey lymphocytes used as the negative control.

The owl monkey is widely distributed throughout South America, and regional variations in coat colour and chromosomal morphology have been described<sup>9</sup>. The polymorphic reaction pattern of W6/32 antibody was found to correlate exactly with chromosomal differences. Nine animals with karyotype VI from Bolivia and two with karyotype VII from Peru were all positive, six animals with karyotype I from Brazil and 23 animals with karyotypes II, III, IV and V from Columbia were all negative (Fig. 3 and Table 1).

Other anti-HLA-A,B,C monoclonal antibodies which showed no polymorphic reactions in humans<sup>10</sup> were screened

against owl monkey lymphocytes of different karyotype. Three different reaction patterns were seen: (1) negative on all cells, (2) identical to W6/32 antibody, and (3) a polymorphic reaction pattern different from the W6/32 antibody. Three antibodies of the last class were identified which all gave similar reaction patterns. Positive reactions were seen with all animals of karyotypes I, II, III, IV, V and VII whereas polymorphic reactions were found with animals of karyotype VI (Table 1). One antibody (PA2.5) was selected for further study and its specificity on all human cells confirmed. PA2.5 antibody reacted equally well with a panel of 20 HLA-A, B, C-bearing human B-cell lines and this binding was equally inhibitable by purified preparations of both HLA-A locus (A2 and A28) and HLA-B locus (B7 and B40) antigens<sup>11</sup>.

As the initial screen (Fig. 1) with the W6/32 antibody against different species involved single animals and by chance, an owl monkey of karyotype VII had been selected, it became important to re-evaluate the reactions on other species. Groups of three New World species (squirrel, spider, cebus) and a single Old World species (rhesus) were tested against W6/32 and PA2.5 antibodies and the results are shown in Table 1. The original conclusions concerning the W6/32 antigenic determinant were confirmed. It was absent on all cebus, squirrel and spider monkeys and present on all rhesus monkeys tested. The

**Table 1** Indirect binding reactions of W6/32 and PA2.5 antibodies on primate lymphocytes

Species	No. of animals tested	W6/32		PA2.5	
		Positive	Negative	Positive	Negative
Spider monkey	12	0	12	8	4
Owl monkey (karyotype VI)	9	9	0	3	6
Owl monkey (karyotype I, II, III, IV, V)	29	0	29	29	0
Owl monkey (karyotype VII)	2	2	0	2	0
Squirrel monkey	20	0	20	20	0
Cebus (brown and white capuchin) monkey	15	0	15	15	0
Rhesus monkey	14	14	0	14	0

PA2.5 antibody gave positive reactions with all rhesus, squirrel and cebus monkeys but was polymorphic in the spider monkey.

The polymorphisms defined by the two monoclonal antibodies in the owl monkey were quite distinct. W6/32 antibody reactions correlated exactly with known differences in karyotype, coat colour and geographical origin. This result is similar to that found for wild mice where individual demes of geographically separated populations had characteristic H-2 antigens<sup>12</sup>. The PA2.5 antibody defined a polymorphism within a presumably interbreeding group of animals that were identical for karyotype, coat colour and W6/32 antibody reactivities. Similarly, the polymorphism defined by the PA2.5 antibody in the spider monkey was not correlated with other known parameters.

**Fig. 2** Indirect trace binding of W6/32 antibody to human, spider monkey and owl monkey lymphocytes as a function of cell number. Assays were as described in the Fig. 1 legend except different cell numbers were used. ●, Owl monkey with karyotype VI; □, owl monkey with karyotype I; ▲, human used as a positive control; △, spider monkey used as negative control.

It is not unexpected that non-polymorphic anti-HLA-A,B,C monoclonal antibodies define polymorphism in other primate species. Highly conserved regions of HLA-A,B,C glycoproteins will not be immunogenic in mice, and it is likely that monoclonal antibodies made in mice will recognise parts of the molecule that can tolerate amino acid substitutions without loss of function and thus have the potential for polymorphism within a species.

Most non-polymorphic anti-HLA-A,B,C monoclonal antibodies we have produced bind to cells of non-human primate species. Comparison of their reactions with different species has provided a simple way of defining different antigenic determinants of the HLA-A,B,C- $\beta_2$ -microglobulin complex. The W6/32 antibody defines a determinant generally restricted to apes and Old World monkeys, the PA2.5 antibody defines a determinant present on apes, Old World monkeys and most New World monkeys. These results indicate that both antigenic determinants originated before the divergence of New and Old World monkeys and it will be interesting to see if they can be detected in tree shrews and the more primitive species of primates.

The high frequency with which antibodies of similar specificity are produced suggests that the number of antigenic determinants is small. This is probably a reflection of the  $\approx 70\%$

**Fig. 3** Indirect trace binding of W6/32 antibody to lymphocytes from owl monkey with seven different karyotypes. Assays were as described in the Fig. 1 legend.

amino acid sequence homology between HLA-A,B,C glycoproteins and the H-2D,K glycoproteins of the mice used to make the antibodies<sup>5,6</sup>. The finding that HLA-A,B,C antigens and their homologues in higher primates are antigenically similar in comparison to mouse indicates a very high degree of amino acid sequence homology. The equivalence with which many anti-HLA monoclonal antibodies bind to cells of non-human primate species and the use of insolubilised W6/32 antibody in the purification of HLA-A,B,C antigens<sup>13</sup> suggest that the homologous antigens of other species may be purified by this method and made available for structural characterisation.

We thank Jack Thomson and Joanne McLean for technical assistance and Dr Walter Bodmer for helpful discussions. F.M.B. was supported by a Marshall Scholarship from the Marshall Aid Commemoration Commission. P.P. was supported by a Junior Fellowship from the Society of Fellows, Harvard University and thanks Dr Jack L. Strominger for provision of laboratory facilities. This research was supported by grants from the UK MRC, and the US NSF and NIH.

## Functional separation *in vivo* of both antigens encoded by H-2 subregion and non-H-2 loci

ANTIGENS coded for by the H-2K, H-2D and H-2I region of the major histocompatibility complex (MHC) of the mouse initiate different *in vitro* responses. I region-coded antigens activate mainly Lyt 1<sup>+</sup> T cells to produce a proliferative response in mixed lymphocyte cultures (MLC), whereas K and D region-coded antigens predominantly stimulate Lyt 2<sup>+</sup> T cells to become cytolytic effector cells<sup>1</sup>. Proliferative responses in MLC and generation of cytolytic T cells *in vitro* can also be induced by minor histocompatibility antigens. For example, Mls-locus products can induce positive MLC responses, but not the generation of cytolytic T cells<sup>2</sup>, whereas H-Y antigen does give rise to anti-H-Y cytotoxic T-cell responses *in vitro*, following *in vivo* priming<sup>3</sup>. Functional *in vivo* studies have shown that H-2K, H-2D and H-2I differences can account for graft rejection<sup>4</sup> and for mortality in graft-versus-host (GvH) reactions<sup>5</sup>. Differences in only minor histocompatibility antigens are sufficient to cause graft rejection<sup>6</sup>, and lethal GvH reaction after allogeneic bone marrow transplantation<sup>7</sup>. Similarly, immunisation with only H-2 or only non-H-2 antigens can induce a state of delayed-type hypersensitivity (DTH) to the immunising antigen, which can be measured with the footpad swelling test<sup>8</sup>. So far, such *in vivo* experiments have shown little or no discrimination between

responses to H-2 subregion antigens and responses to non-H-2 antigens. We have used a DTH assay to study the occurrence of T-effector cells after *in vivo* immunisation with different histocompatibility antigens. We show here that DTH T-effector cells generated in GvH and host-versus-graft (HvG) reactions are specific for largely different sets of histocompatibility antigens, with selective stimulation by H-2I and Mls-locus antigens in GvH conditions.

We have developed a simple DTH assay which can be used to measure the development of T-effector cells induced by histocompatibility antigens during a GvH reaction<sup>9,10</sup>. The assay is based on secondary transfer of lymphoid cells from animals undergoing a GvH reaction, and subsequent testing of the secondary recipients for DTH reactivity to the histocompatibility antigens which evoked the GvH reaction. Briefly, lymphoid cells from mice which have been irradiated and reconstituted with allogeneic spleen cells, are transferred intravenously (i.v.), at various intervals after reconstitution, into normal secondary recipients syngeneic to the original spleen cell donor. The secondary recipients are challenged in the right hind foot with  $2 \times 10^7$  spleen cells syngeneic to the original irradiated recipients. The DTH response to this challenge is measured as the difference in thickness of the hind feet 24 h later. The specific increase in foot thickness is calculated as the relative increase in foot thickness of the immune mice minus the relative increase in foot thickness of control mice which have only received the challenge. The swelling of challenged control mice varies between 12 and 20%. Using this assay we studied the capacity of

**Table 1** Anti-host immune reactivity in lethally irradiated recipients after spleen cell transplantation across H-2-subregion differences

Inoculum	Recipient	H-2 subregion coding for immunising antigen*	Challenge	H-2 subregion coded antigens of cells used for challenge	DTH Response
B10.A	B10.AQR	K	B10.AQR	K	3.2 ± 1.6

B10.AQR	B10.A × B10.T(6R)	K + I	B10.T(6R)	I	32.2 ± 2.9
B10.AQR	B10.A × B10.T(6R)	K + I	B10.A	K	3.4 ± 3.0
A.TH	A.TL	I(+Tla)	A.TL	I(+Tla)	31.4 ± 2.6
A.TH	A.SW	D(+Tla)	A.SW	D(+Tla)	-0.3 ± 1.4

GvH reactions were elicited by i.v. injection of  $5 \times 10^7$  spleen cells (inoculum) into lethally irradiated recipient mice. Recipients were lethally irradiated (750 rad) within 4 h before reconstitution with the spleen cell inoculum; 5 d after reconstitution two-thirds of the total cell yield obtained from spleen, inguinal, axillary and mesenteric lymph nodes of a recipient mouse were transferred i.v. to a secondary recipient which was syngeneic to the original spleen cell donor. Lymphoid cells from all primary recipients of a particular combination were pooled before secondary transfer. Challenge was carried out with  $2 \times 10^7$  (50 µl) spleen cells (treated with mitomycin C (Kyowa Hakko Kogyo)  $100 \mu\text{g ml}^{-1}$  for 30 min at 37 °C) injected s.c. into the instep of the right hind foot of the secondary recipients. At 24 h after challenge DTH responses were measured. Control mice only received a challenge dose. The swelling of these control mice was 12–20%. DTH responses are expressed as the specific percentage increase in foot thickness, as described previously<sup>9</sup>. Figures represent the arithmetic mean ± 1 s.e.m. of five mice.

\* H-2-subregion difference between spleen cell donor and irradiated recipient mice. The origin of H-2 subregions (K, I-A, I-B, I-C, D) for the strains are as follows: A.TH, ssssd; A.SW, sssss; A.TL, skkdd; B10.A, kkkdd; B10.AQR, qkkdd; B10.T(6R), qqqdd.

**Table 2** Anti-host immune reactivity in lethally irradiated recipients after spleen cell transplantation across Mls-locus differences

Inoculum	Recipient	Peak MLC response	Challenge	Mls locus-coded antigen of cells used for challenge	Peak DTH response
BALB/c	BALB/c × DBA/2	24,000 ± 850 (4)	DBA/2	Mls <sup>a</sup>	25.5 ± 0.7 (5)
BALB/c	BALB/c × DBA/2	—	B10.D2	Mls <sup>b</sup>	0.5 ± 1.2 (5)
DBA/2	BALB/c × DBA/2	630 ± 280 (3)	BALB/c	Mls <sup>b</sup>	10.6 ± 2.2 (3)
AKR/FuRdA	C3H/f	22,300 ± 1300 (3)	C3H/f	Mls <sup>c</sup>	25.8 ± 1.8 (7)
AKR/FuRdA	C3H/f	—	B10.BR	Mls <sup>b</sup>	2.9 ± 1.1 (7)
C3H/f	AKR/FuRdA	38,000 ± 2900 (4)	AKR/FuRdA	Mls <sup>a</sup>	26.7 ± 2.0 (7)
C3H/f	AKR/FuRdA	—	B10.BR	Mls <sup>b</sup>	1.9 ± 1.7 (7)

GvH reactions were elicited by i.v. injection of  $5 \times 10^7$  spleen cells (inoculum) into lethally irradiated recipient mice. The designation for H-2 haplotype and Mls locus for the strains are as follows: BALB/c, H-2<sup>d</sup>, Mls<sup>b</sup>; DBA/2, H-2<sup>d</sup>, Mls<sup>a</sup>; BALB/c × DBA/2, H-2<sup>d/d</sup>, Mls<sup>b/a</sup>; B10.D2, H-2<sup>d</sup>, Mls<sup>b</sup>; AKR/FuRdA, H-2<sup>k</sup>, Mls<sup>a</sup>; C3H/f, H-2<sup>k</sup>, Mls<sup>c</sup>; B10.BR, H-2<sup>k</sup>, Mls<sup>b</sup>. Recipients were lethally irradiated (850 rad) before reconstitution. At different intervals after reconstitution a number of spleen cells equivalent to one spleen was transferred i.v. into secondary recipients which were syngeneic to the original spleen cell donors. Peak one-way MLC responses are expressed as specific counts per min. Figures represent the arithmetic mean ± 1 s.e.m. of a quadruplicate microculture. The day of peak MLC response is given in parentheses. Each culture consisted of  $5 \times 10^5$  responder spleen cells and  $5 \times 10^5$  stimulator (treated with 25 µg mitomycin C per ml) spleen cells. Activity of responder cells alone was 250–1,200 c.p.m. and activity of mitomycin C-treated stimulator cells 50–300 c.p.m. Background activity was 35 c.p.m. Details of the technique will be published elsewhere<sup>15</sup>. Challenge was carried out as described in Table 1 legend. Peak DTH responses are expressed as the specific percentage increase in foot thickness. Figures represent the arithmetic mean ± 1 s.e.m. of five mice. The day of peak DTH response is given in parentheses.

**Table 3** Anti-graft immune reactivity after immunisation with spleen cells differing at H-2 subregions or minor histocompatibility loci

C3H/f	AKR/FuRdA	B10.BR	Mls <sup>b</sup>	28.8 ± 1.5

Immunisation was carried out with  $1 \times 10^7$  spleen cells s.c., equally distributed over the inguinal areas by means of a 28-gauge needle. For the origin of H-2 subregions and Mls locus see legends to Tables 1 and 2. Challenge was carried out as described in the Table 1 legend. DTH responses were assayed 5 d after s.c. immunisation of the responder mice and expressed as the specific percentage increase in foot thickness. Figures represent the arithmetic mean  $\pm$  1 s.e.m. of five mice.

H-2 subregion-coded antigens and minor histocompatibility antigens to induce such T-effector cells after (semi-)allogeneic spleen cell transplantation in lethally irradiated mice. These results were correlated with the capacity of the same antigens to induce DTH-related T-effector cells during a HvG reaction.

In lethally irradiated congenic mice, reconstituted with allogeneic spleen cells which were different at the whole or part of the H-2 complex, it could be demonstrated that the transferable anti-host DTH reactivity is directed exclusively to the I region of the H-2 complex; K and D subregion-coded antigens do not induce anti-host DTH T-effector cells (Table 1). H-2 compatible, non-H-2-incompatible spleen cell transplantation in lethally irradiated hosts revealed that antigens encoded by the Mls locus can also elicit the development of a transferable anti-host-directed DTH reactivity (Table 2). Mls<sup>a</sup> and Mls<sup>c</sup> coded antigens initiated both a positive MLC response and a distinct GvH-related DTH reactivity. Mls<sup>b</sup>-locus antigens, on the other hand, were not able to initiate *in vitro* proliferation; this was associated with a marginal and short-lasting GvH-related DTH reactivity (Table 2).

Minor histocompatibility antigens other than Mls-locus products did not contribute to the expression of the anti-host DTH reactivity. This was shown by B10.D2 challenge of secondary BALB/c recipients of cells activated to DBA/2 non-H-2 antigens, and by B10.BR challenge of C3H/f and AKR recipients of cells activated to AKR and C3H/f, respectively. In this experiment the cells used for challenge had different Mls-locus antigens from the irradiated recipients. As there is extensive cross-reactivity in various mouse strains between non-H-2 alloantigens other than Mls-locus products<sup>11</sup>, challenge with H-2-compatible, Mls locus-different spleen cells would demonstrate the contribution of these non-H-2 alloantigens in the expression of GvH-related DTH reactivity. No significant anti-host DTH reactivity could be elicited after challenge with B10.D2 or B10.BR spleen cells (Table 2). Therefore, non-H-2 alloantigens other than Mls locus-coded products probably do not evoke anti-host DTH reactivity. Apparently, Mls-locus products and I-region antigens have a similar capacity for inducing anti-host-directed DTH T-effector cells. K and D region antigens and non-H-2 antigens other than Mls-locus products are much less able to do so.

In contrast, in HvG reactions induced by subcutaneous (s.c.) injection of allogeneic spleen cells, K, D and I region-coded antigens as well as non-H-2 histocompatibility antigens could give rise to anti-graft DTH T-effector cells (Table 3). Also, minor histocompatibility antigens other than Mls-locus products contribute to the expression of the anti-graft DTH reactivity (Table 3). According to the work of Vadas *et al.*<sup>12</sup> there may be two subsets of T cells mediating DTH: Lyt 1<sup>+</sup> and Lyt 2<sup>+</sup> T cells, which are restricted by the I or the K and D regions of the MHC, respectively. Probably, in GvH conditions only Lyt 1<sup>+</sup> DTH

T-effector cells are activated (anti-H-2I and anti-Mls response) and in HvG conditions both Lyt 1<sup>+</sup> and Lyt 2<sup>+</sup> DTH T-effector cells are activated. This might be related to the frequency of T cells reactive to the various histocompatibility antigens<sup>13,14</sup>.

We thank Drs O. Vos, Th. H. van der Kwast, H. von Boehmer and K. Fischer-Lindahl, and Mr N. H. C. Brons for valuable contributions. The investigation was supported by the Netherlands Foundation for Medical Research (FUNGO).

## A candidate for the permeability pathway of the outer mitochondrial membrane

UNLIKE most other membranes, the outer mitochondrial membrane seems to be freely permeable to various small molecules and has therefore been called 'leaky'. The intactness of this membrane is demonstrated by observations<sup>1-4</sup> which show it to be impermeable to large polymers. This 'sieving' property is consistent with the presence of size-selecting units such as channels. Parsons and co-workers<sup>5,6</sup> have published electron micrographs showing what looked like channels in the outer membrane of mitochondria (particularly those from plants), and recent X-ray diffraction studies by Mannella and Bonner<sup>7</sup> have confirmed the existence of structures of similar dimensions to those seen in the electron micrographs. I now report the extraction of channel-forming material from the outer membrane of rat liver mitochondria. This material has properties which are

**Fig. 1** Incorporation of Triton X-100-solubilised VDAC into a planar bilayer. An unmodified planar lipid bilayer was made (see Table 1 legend) with a conductance of  $\sim 10$  pS (membrane was 0.15 mm in diameter) in the presence of 1 M KCl, 5 mM CaCl<sub>2</sub>. Five microlitres of a 2% Triton solution containing VDAC from rat liver mitochondria (a purified fraction—the method of purification will be described elsewhere) was added to the front compartment. A transmembrane voltage of 10 mV (the rear compartment being positive) was applied continuously using the voltage clamp set-up previously described<sup>8</sup>. After a few minutes, the insertion of channels is observed as distinct increases in membrane conductance. The channels are of uniform size. In the middle of the record the scale was reduced by a factor of 4, so the scale on the right-hand side of the graph refers to the right-hand side of the record while that on the left-hand side refers to the left side of the record. The chart speed was constant throughout.

essentially identical with those reported previously<sup>8</sup> for voltage-dependent anion-selective channels (VDAC) from mitochondria of *Paramecium*. VDAC could be responsible for the permeability of the outer membrane to small molecules and may be involved in regulating mitochondrial metabolism.

The VDAC channels previously described (from *Paramecium* mitochondria) displayed the following properties after insertion into planar lipid bilayers: (1) The permeability produced in the bilayer is due to channels of uniform size. (2) These channels conduct anions better than cations of comparable size and charge. (3) The channels switch to lower conducting states (close) when the transmembrane voltage is increased both in the positive and negative direction: the voltage range at which this switching from high to low conductance occurs is narrow so that the voltage dependence is steep. These properties characterise VDAC and distinguish it from all other conductances that have been observed in bilayers. These properties are constant from preparation to preparation and, remarkably, from species to species. Hence, the term VDAC is used here to refer to all the channels displaying these characteristic properties.

Channel-forming activity was assayed in two ways as described in Table 1 legend and conductance in the bilayer was checked for the characteristic properties described above. In the first assay method the sample (suspended in hexane) was layered on the surface of the aqueous phases to generate monolayers from which the bilayer was formed (no detergent was used). The numbers of VDAC channels in the resulting bilayer are a measure of VDAC activity. Results obtained with this method are shown in the third column of Table 1. The second method involved extracting a sample with Triton X-100 and adding an aliquot of this extract to the medium bathing an unmodified lipid bilayer. The rate of VDAC channel insertion from the medium per unit time is a measure of the VDAC content of the original sample (last column in Table 1). Both methods yield VDAC channels with the same characteristic properties. Therefore the presence of the detergent has no discernible effect on VDAC.

Table 1 shows that mitochondria from a wide variety of eukaryotes have VDAC channels. To date all mitochondria tested have shown VDAC activity. In addition, Table 1 shows that VDAC is not present in rat liver microsomes. The low activity in the microsomal fraction can be accounted for by a 1% mitochondrial contamination. The large standard deviations shown in the table do not indicate irreproducibility in obtaining VDAC activity. Rather, there was a large variation in the number of channels incorporated in the bilayer using the same preparation on the same day. (This type of variability is not unusual when conducting elements are inserted into planar lipid bilayers.) Despite quantitative uncertainty, there is no doubt that VDAC is present in all these organisms.

Figure 1 shows a time course of the current (number of ions crossing the membrane per unit time) which flowed across the membrane after the addition of an extract of rat liver mitochondria to the aqueous phase in which the membrane was bathed. The driving force for ion flow was a 10-mV transmembrane potential. The current increased by distinct jumps of uniform size. The rise time of the jumps was shorter than we can accurately measure,  $< 50$   $\mu$ s—a characteristic property of channels in general. The rate of channel insertion was fairly constant.

The voltage dependence of VDAC is illustrated in Fig. 2. When the driving force was increased from 10 to 40 mV the current increased fourfold but then decreased to a new lower level. This was due to the switching of VDAC channels from a high to a low conductance state (channels close). When the voltage was returned to 10 mV the channels returned to the high conductance state (channels open). Note that the rate for VDAC opening is much faster than that for closing. The same behaviour

**Table 1** Location of VDAC at the organelle level

Source	Major organelle present in fraction	VDAC activity	
		Channels per membrane	Channels per min per mg*
<i>Paramecium</i>	Mitochondria	500 $\pm$ 300	
	Cilia	0	
	Pellicle	20 $\pm$ 20	
Rat liver	Mitochondria	200 $\pm$ 100	
	Microsomes	2 $\pm$ 1	0
Rat heart	Mitochondria		330
Beef heart	Mitochondria		370
<i>Neurospora</i>	Mitochondria	700 $\pm$ 600	1,000 $\pm$ 500
Yeast	Mitochondria	50 $\pm$ 50	
Lobster	Axolemma	0	0

Mitochondrial fractions from rat, beef, *Neurospora* (wall-less mutant of *N. crassa*, provided by Dr Gene Scarborough) and yeast were produced by standard procedures. The rat liver microsomes were obtained by centrifuging the post-mitochondrial supernatant at 100,000g for 30 min and taking the top part of the translucent pellet. The *Paramecium* results are those reported previously<sup>8</sup>. Purified lobster axolemma was prepared as described by Barnola *et al.*<sup>16</sup>. Channel-forming activity was assayed by two methods. The first was that described previously<sup>8</sup>. [Mitochondria were sonicated with a 25-fold excess of soybean phospholipid, lyophilised and suspended in hexane (1% w/v). The suspension was layered on the aqueous phases to form monolayers which were then used to produce bilayers by the method of Montal and Mueller<sup>17</sup>.] Results of this assay are expressed as channels per membrane  $\pm$  s.d. In the second method, Triton X-100 was added to the sample to a final concentration of 2% (v/v) (the protein concentration was not greater than 10 mg ml<sup>-1</sup>). A planar bilayer was made by the method of Montal and Mueller<sup>17</sup> following the technique previously described<sup>8</sup>. (Soybean lipids were used after purification as previously described<sup>18</sup>.) An aliquot of this solution (5 or 10  $\mu$ l) was added to the front compartment. The rate of incorporation of channels into the bilayer, normalised per unit amount of protein added, is a measure of the VDAC activity in the sample (last column). (Note that the Triton extract should be warmed up to room temperature for at least 1 h before assay.) Normalisation is not required in the first assay because the ratio of protein to lipid in the membrane forming solution is kept at a constant 1:25 (w/w). \* Rate of VDAC channel insertion from medium per unit time per mg protein.

**Fig. 2** The voltage-dependent conductance of VDAC. The upper traces show the current and the lower traces the voltage as a function of time. VDAC was inserted as described in Fig. 1. After a certain time the amount of VDAC inserting, for short time periods, is small compared with what has already inserted. Therefore, the conductance can be considered constant for short periods so that conductance changes caused by voltage are not due to channels inserting into the bilayer. On the left-hand graph (a), the voltage was increased from 0 to 10 to 40 mV. The current was constant at 0 and 10 mV. When the voltage was increased to 40 mV, initially, the current increased ohmically indicating no conductance change. Then the current decreased as the VDAC channels closed. On the right-hand graph (b), the membrane was clamped at 40 mV until the current level was fairly constant (channels had turned off). Then the voltage was dropped to 10 mV. The current initially dropped to  $\frac{1}{4}$  of its value (ohmic behaviour) and then increased due to VDAC channels opening. Note the difference in time scale between closing and opening rates. The records were first stored using a digital storage oscilloscope (Gould OS 4000) and then transcribed onto a chart recorder.

was seen in VDAC channels from *Paramecium* mitochondria<sup>8</sup>. This was also observed with VDAC channels from *Neurospora crassa* and *Saccharomyces cerevisiae*.

The anion selectivity was verified by measuring the reversal potential of the membrane conductance in the presence of a salt concentration gradient (KCl at 1.0 and 0.1 M). A value of 13 mV positive in the high salt side was measured for material extracted from rat liver—close to that observed in VDAC from *Paramecium* (Fig. 5b of ref. 8).

VDAC's large single channel conductance (0.45 nS in 0.1 M KCl and 4.5 nS in 1.0 M KCl) indicates that the pore size is large. A simplified calculation assuming the specific conductance in the channel to be the same as in solution yields a pore diameter of  $\sim 15$  Å. Large pore size is also suggested by the fact that acetate<sup>8</sup>, sulphate<sup>8</sup>, fumarate and succinate (unpublished observations) easily cross the channel. (Fumarate is five times less permeable than  $\text{Na}^+$ .)

VDAC was shown to be located in the outer membrane of rat liver mitochondria by fractionating the mitochondrial membranes into outer and inner (fractions B and P) by the method of Parsons *et al.*<sup>9</sup>. Cross contamination was monitored using cytochrome oxidase activity<sup>10</sup> as a measure of the amount of inner membrane present in the outer membrane fraction and NADH-cytochrome *c* reductase activity<sup>11</sup> as a marker for outer membrane. VDAC activity was assayed by following the rate of channel insertion into a lipid bilayer as described above. The results are summarised in Table 2. The marker enzymes confirm good purification of inner and outer membranes with little cross-contamination. VDAC activity is sixfold higher in the

**Table 2** Location of VDAC in the mitochondrion

	Inner membrane fraction	Outer membrane fraction	Activity ratio outer/inner
Cytochrome oxidase ( $\mu\text{mol}$ cytochrome <i>c</i> $\text{mg}^{-1} \text{min}^{-1}$ )	1.04	0.063	0.06
NADH-cytochrome <i>c</i> reductase ( $\mu\text{mol}$ cytochrome <i>c</i> $\text{mg}^{-1} \text{min}^{-1}$ )	0.24	6.0	25
VDAC (channels $\text{min}^{-1} \text{mg}^{-1}$ )	$200 \pm 200(7)^*$	$1,200 \pm 1,000(6)$	6

\* Mean  $\pm$  s.d. with number of assays in parentheses.

outer membrane fraction than in the inner membrane. The large standard deviation is again due to the variability inherent in the assay method. Despite this variability, VDAC is clearly located in the outer mitochondrial membrane. (Its absence from the inner membrane has not been demonstrated.)

Thus the large size of VDAC, its location in the outer mitochondrial membrane and its presence in a wide variety of organisms, indicate that VDAC may be the channel making the outer membrane permeable to small molecules. It is conceivable that the voltage-dependence of VDAC may regulate the flow of metabolites between the cytoplasm and the inner mitochondrial membrane. The small transmembrane potential needed to turn off most of the channels could be generated by a Donnan potential, changes in surface or dipole potentials mediated perhaps by changes in enzyme activity or metabolite concentration.

Interestingly, a similar channel has been isolated from the outer membrane of *Escherichia coli*<sup>12,13</sup>. Genetic studies<sup>14</sup> and transport measurements of the reconstituted material in vesicles<sup>15</sup> show that there is a channel in the outer membrane of *E. coli* that allows small molecules up to the size of a triose to cross that outer membrane. Benz *et al.*<sup>12</sup> and Schindler *et al.*<sup>13</sup> have incorporated this protein into planar lipid bilayers and shown that it forms channels that are somewhat smaller than VDAC, weakly selective for cations over anions and voltage dependent, in a similar way to VDAC, but at high transmembrane voltages (150–200 mV compared with 15–30 mV for VDAC). This parallelism may indicate a common primordial channel.

I thank Dr Alan Finkelstein for assistance and advice, and Drs Efraim Racker, Donald Parsons and Carmen Mannella for critical comments. This work was supported by grants from the Scottish Rite Schizophrenia Research Program and the NIH.

## A stable chemiluminescent-labelled antibody for immunological assays

RADIOISOTOPES, in particular  $^{125}\text{I}$ , have been used for many years as labels for monitoring the distribution of reagents in immunological assay systems. Satisfactory labelled derivatives are not always easily produced as iodination frequently produces severe molecular disruption. Moreover, iodinated proteins have a limited shelf life and sometimes require extended counting times for accurate quantitation. Recently, non-radioactive labels such as bacteriophages<sup>1,2</sup>, enzymes<sup>3,4</sup>, stable free radicals<sup>5</sup> and fluorescent groups<sup>6</sup> have been used in attempts to overcome some of these problems. We describe here the successful labelling of antibodies to rabbit IgG with a chemiluminescent molecule and the development of an immunological assay using chemiluminescence as a means of monitoring reagent distribution.

The luminescence of luminol (5-amino-2,3-dihydrophthalazin-1,4-dione) occurs during oxidation in alkaline conditions<sup>7</sup> in the presence of certain inorganic ions or molecules<sup>8</sup> (for example  $\text{MnO}_4^-$ ,  $\text{I}_2$ ,  $\text{Fe}(\text{CN})_6^{3-}$ ,  $\text{Cu}^{2+}$  and  $\text{OCl}^-$ ). In such conditions, luminol takes part in a reaction which generates an excited product molecule. This subsequently becomes de-excited by several mechanisms<sup>9</sup>, one of which is the emission of photons. The quantum yield for this process is approximately 0.015 in aqueous conditions<sup>10</sup>. A photon counter built in our laboratory<sup>11</sup> is capable of detecting  $10^{-18}$  mol of luminol.

An IgG fraction of a sheep anti-rabbit IgG antiserum prepared by sodium sulphate precipitation was reacted with a diazonium salt of luminol. Diazotisation involved a marked reduction in quantum yield (Table 1), possibly as a result of polymerisation of diazoluminol. A further small reduction took place following overnight incubation at pH 8.6 as required for the coupling reaction, although there was no further loss of quantum yield as a result of the coupling procedure itself. The incorporation of diazoluminol into conjugate with IgG was dependent on the concentration of reactants (Table 2). Using a 100-fold molar excess of luminol it was possible to incorporate up to 80% of the ligand, although it was found that at uptake

**Table 1** Recovery of luminescence during coupling of luminol to IgG

Stage of coupling	Total recovered counts	% Initial luminescence
Initial	$5.9 \times 10^{11}$	100
Diazoluminol*	$7.9 \times 10^9$	1.34
Diazoluminol†	$3.8 \times 10^9$	0.67
Lumino-IgG conjugate	$4.0 \times 10^9$	0.70

Luminol-IgG conjugate was prepared by diazotising 200 mg of luminol in 20 ml ice-cold 2.4 M HCl with 200 mg  $\text{NaNO}_2$ . Ice-cold borate buffer (50 ml 0.5 M, pH 8.5) was added and the pH adjusted to 8.5. Fourteen ml of this solution was added to 8.5 ml of a solution containing 1 g of an IgG fraction, prepared by sodium sulphate precipitation of a sheep anti-rabbit IgG antiserum (code SB 82/2) in borate buffer (0.5 M, pH 8.5). The molar ratio of luminol: IgG was calculated to be approximately 30:1. The mixture was allowed to stand for 18 h at 4 °C to enable coupling to occur. Unconjugated luminol was removed by extensive dialysis against 0.2 M borate buffer pH 8.0 and stored as 0.5 ml aliquots at -20 °C. Samples (10  $\mu\text{l}$ ) were removed at stages during the preparation of the conjugate and diluted (1/100–1/1,000) with 0.1 M NaOH. Luminescence was measured as follows. Aliquots (10  $\mu\text{l}$ ) of the diluted samples were added to 1 ml of 0.1 M NaOH in polystyrene tubes. 5.4 mM  $\text{H}_2\text{O}_2$  (100  $\mu\text{l}$ ) was added and after mixing the reaction tube was placed in the reaction chamber of the digital photon counter. The reaction was initiated by addition of 1 ml 1.0 mM NaOCl in 0.1 M NaOH solution. Counts were accumulated for a period of 20 s. After correction for volume changes values were calculated to give total recovered counts.

\* Immediately on preparation.

† After overnight incubation at 4 °C in 0.2 M borate buffer (pH 8.5).

**Fig. 1** Time course of light emission from luminol (●) and luminol-IgG conjugate (○). The luminol-IgG conjugate was prepared as described in Table 1, and purified before use by affinity chromatography using an immunoabsorbent (ImAd) prepared from rabbit IgG coupled to a diazonium salt of powdered cellulose<sup>12</sup>. After reaction overnight at 4 °C the ImAd-antibody complex was washed free of unbound label using 0.05 M veronal buffer, pH 8.2 containing (w/v) 0.1% bovine serum albumin, 0.05% sodium azide 0.002% non-immune sheep IgG (NISH buffer). After washing with water to remove the buffer, luminol-labelled antibody was eluted by reduction of the pH to 2.0. The supernatant was buffered to pH 8.2 using an equal volume of NISH buffer at double strength with respect to all constituents. The luminescence was quantitated as described in Table 1. In this case the rate of light emission was plotted on a chart recorder. Values taken from this graph were plotted as the natural logarithm against time (in seconds) from the start of the reaction.

ratios in excess of 40 mol luminol per mol IgG the product precipitated on storage. The labelled product was freed of unreacted luminol by extensive dialysis and purified subsequently by affinity chromatography using a rabbit IgG immunoabsorbent. The purified product prepared by reacting IgG of the sheep anti-rabbit IgG antiserum with a 30-fold molar excess of diazoluminol contained 22 mol luminol per mol IgG.

Figure 1 compares the time courses of light emission from luminol and the luminol-antibody conjugate. The two materials were tested in identical conditions as the rate constant for light emission is dependent on the concentration of  $\text{H}_2\text{O}_2$  and catalyst<sup>8</sup>. Luminol conjugated to IgG had a significantly higher rate constant than luminol itself. When the luminescent material was the limiting reactant, the decay phase of the light-emitting reaction was an exponential curve with a rate constant of  $0.073 \text{ s}^{-1}$  for conjugated luminol and a value of  $0.014 \text{ s}^{-1}$  for luminol itself. The reason for the increase in reaction rate of conjugated luminol is not yet clear. It is possible that some structural alteration in the ligand has taken place.

In these experiments we have quantified the luminescent material by measuring accumulation of counts during a 20-s period. It is apparent from Fig. 1, however, that in the conditions used for these experiments, the rate of emission of light from the reaction is first order with respect to the luminol concentration. It is therefore possible to quantify the luminescent material by measuring the maximum reaction rate over a short period, for example 2 s.

The immunological reactivity of the luminol-labelled sheep anti-rabbit IgG antibody was assessed by a radioimmunoassay using solid phase rabbit IgG and  $^{125}\text{I}$ -labelled sheep anti-rabbit IgG antibody. Through a series of dilutions (1/1 to 1/1,000 with respect to the antiserum) no difference could be detected between the luminol-labelled antibody and unlabelled sheep anti-rabbit IgG antibody in ability to bind antigen.

Using the luminol-labelled sheep anti-rabbit IgG antibodies it was possible to develop a two-site assay<sup>13</sup> for rabbit IgG. The procedure involved extraction of rabbit IgG on to polystyrene tubes coated with unlabelled sheep anti-rabbit IgG antibody. Uptake of the antigen was then determined by reacting with the labelled antibodies. Figure 2 shows standard curves obtained using luminol-labelled antibodies immediately after preparation (a) and after 9 months storage at  $-20^{\circ}\text{C}$  (b) with a curve obtained with freshly prepared  $^{125}\text{I}$ -labelled sheep anti-rabbit IgG antibody. The luminol-labelled antibody produced an assay of similar sensitivity to that obtained with the iodinated antibody but also showed no apparent loss of activity after storage for 9 months.

These results show that antibody molecules may be labelled with luminol without altering their immunological reactivity, and, despite losses in the quantum yield from the luminescent molecule, these antibodies may be used to develop a satisfactory immunological assay. Moreover, the time course of light emission from the labelled derivative is rapid enough for accurate measurement to be made within 2 s of the initiation of the luminescent reaction. Finally, the stability of the labelled antibody is such that assays may be carried out over long periods (at least 9 months) with no apparent loss of performance.

The development of chemiluminescent labels offers considerable potential for improvements in immunoassay technology and in other areas of biochemistry and histology where there is a need for biologically active high specific activity labels. Because they are stable, such reagents can be produced in bulk. This has important implications in terms of cost and quality control of assays. The ability to carry out extremely rapid

**Fig. 2** Standard curves obtained in a two-site assay of rabbit IgG using luminol-labelled and  $^{125}\text{I}$ -labelled (▲) sheep anti-rabbit IgG antibody. Assays were carried out with freshly prepared luminol-labelled antibody (●) and the same reagent after nine months storage at  $-20^{\circ}\text{C}$  (■). Antibodies purified from antiserum SB 82/2 by means of affinity chromatography with rabbit IgG ImAd, were incubated in polystyrene tubes in 0.1 M carbonate buffer pH 9.6 at a dilution equivalent to 1:85 of the original serum, to prepare a solid phase derivative<sup>14</sup>. After coating, the tubes were washed with 0.1% bovine serum albumin in 0.15 M sodium chloride solution containing 0.1% thiomersal, and stored empty at  $-20^{\circ}\text{C}$ . In the assay procedure, standard solutions of rabbit IgG in NISH buffer (half strength) were added to the tubes and incubated overnight at  $4^{\circ}\text{C}$ . Then, either luminol or  $^{125}\text{I}$ -labelled antibodies purified as described in Fig. 1 were added. After a further overnight incubation at  $4^{\circ}\text{C}$ , the tubes were washed again in NISH buffer (half strength) and either counted in an automatic gamma spectrometer or assayed for luminescence activity as described in Table 1.

**Table 2** Incorporation of luminol into luminol-IgG conjugate

Initial luminol/IgG ratio	$A_{450}^a$	$A_{450}^b$	TCA precipitated <sup>c</sup> (%)	Molar ratio of luminol: IgG <sup>d</sup>
0	0.000	0.000		
5	0.172	0.098	43.0	2.15
10	0.199	0.067	66.3	6.63
20	0.228	0.074	67.5	13.5
50	0.419	0.077	81.6	40.8
100	0.758	0.127	83.25	83.25

Luminol and diazoluminol are both soluble in TCA solutions. Both compounds absorb strongly at 450 nm.

<sup>a</sup> Absorbance (450 nm) of conjugate after coupling, before dialysis.

<sup>b</sup> Absorbance (450 nm) after precipitation of protein by addition of an equal volume of 15% trichloroacetic acid (TCA). The supernatant was buffered to pH 8.5 and a correction made for volume change.

<sup>c</sup>  $(1 - b/a) \times 100\%$ .

<sup>d</sup>  $c/100 \times \text{initial ratio}$ .

quantitation of label is likely to prove an important factor in the organisation of assays involving large sample numbers, for example screening programmes. Finally, the quantitation of chemiluminescence offers a major advantage, particularly with respect to sensitivity, over other non-isotopic labels (for example fluorescence) in that detection is made against a background which is theoretically zero.

We acknowledge an equipment grant from the SRC. J.S.A.S. was in receipt of an MRC research scholarship.

## Introns in the chicken ovalbumin gene prevent ovalbumin synthesis in *E. coli* K12

It has recently been discovered that some eukaryotic genes are split, the mRNA coding sequences (exons) being interrupted by intervening sequences (introns) of unknown function<sup>1-3</sup>. In all cases examined, these split genes are transcribed into an RNA precursor which is then matured by a splicing mechanism<sup>4-6</sup>. Because this type of gene structure has not previously been found in bacteria, it is generally believed that split genes cannot be expressed in *Escherichia*, but there are no facts to support this assumption. We demonstrate here that the presence of introns in the chicken ovalbumin gene prevents ovalbumin synthesis in *E. coli* K12.

The chicken ovalbumin gene is split into eight exons (designated 1 to 8) separated by seven introns (named A to G)<sup>2,7-17</sup>. It

is transcribed into an RNA precursor (at least) 7,600 nucleotides long, which is then spliced into ovalbumin mRNA (ov mRNA)<sup>5,6</sup>. We have isolated, by molecular cloning in *E. coli* K12, chicken DNA segments which carry part of the gene or the entire gene<sup>7-14</sup>. We have also constructed plasmids which carry synthetic double-stranded DNA sequences complementary to ov mRNA (ov ds cDNA) and are devoid of introns<sup>17</sup>. In one of these plasmids, pOMP2, the ovalbumin sequence was fused in phase at the beginning of the *E. coli* gene coding for  $\beta$ -galactosidase, the fifth amino acid of ovalbumin (from the NH<sub>2</sub>-terminal part of the protein) being connected to the seventh amino acid of  $\beta$ -galactosidase<sup>18</sup>. We have shown (as have others<sup>19</sup>) that *E. coli* cells harbouring the recombinant plasmid synthesise large amounts of an ovalbumin-like product, which resembles ovalbumin in size and reactivity with ovalbumin-specific antibodies. We have manipulated the fused *lac*-ovalbumin sequence and introduced into it some of the introns present in the natural gene so as to assess their influence on the synthesis of the ovalbumin-like product.

There are two sites for the restriction endonuclease *Sst*I in ov ds cDNA, 378 base pairs apart, located at nucleotides 116 and 494 in the ov mRNA sequence<sup>8,11</sup>. In the natural gene, these sites are located in exons 1 and 4, respectively, and separated by 1,612 base pairs which include introns B, C and D (refs 8, 11). The substitution of this 1,612-base pair fragment in place of the 378-base pair one in the *lac*-ovalbumin sequence will thus result in the introduction of three introns of the natural gene. This was achieved as depicted in Fig. 1: because pOMP2 has an additional *Sst*I site (in a sequence originating from phage  $\lambda$  (ref.

18)) we first extracted the *lac* regulatory region with the *lac*-ovalbumin fusion by digestion with *Hha*I. The resulting 2.67-kilobase fragment was introduced into partially digested pBR322, cut only once by *Hha*I. The resulting plasmids, like pOMP2, produced large amounts of ovalbumin-like protein in *E. coli*. One of these, pOMP21, was selected for further studies. The 378-base pair *Sst*I fragment of pOMP21 was substituted by the 1,612-base pair *Sst*I fragment extracted from the cloned *Eco*RI fragment 'b' of the ovalbumin gene<sup>8</sup>. We thus obtained pOMP23 in which introns B, C and D were correctly orientated for transcription from the *lac* promoter (see Fig. 1 legend for mapping of this plasmid). *E. coli* harbouring pOMP23 was then tested for the production of ovalbumin-like protein by a radioimmunoassay. As shown in Fig. 2, pOMP21 (as pOMP2) makes large amounts of an ovalbumin-like product, whereas no ovalbumin-like product is detectable in the pOMP23 assay, even with concentrated bacterial extracts—at least 3,000-fold less than pOMP21, that is, less than three molecules per bacterium in the experiment shown.

We next investigated whether this negative result could be due to inadvertent mutational changes during the construction of pOMP23. The *Sst*I 1,612-base pair fragment was excised from pOMP23 and replaced by the 378-base pair *Sst*I fragment extracted from ov ds cDNA. Where the insertion occurred in the proper direction, pOMP26 again produced large amounts of ovalbumin-like protein (not shown). This does not exclude the possibility that mutations occurred in the 1,612-base pair fragment. The latter, however, was isolated from the same cloned *Eco*RI 'b' fragment of the ovalbumin gene which was sequenced

**Fig. 1** Introduction of introns B, C and D into the *lac*-ovalbumin sequence. *a*, Restriction maps of the fused *lac*-ov ds cDNA sequence and of the ovalbumin *Eco*RI 'b' fragment (see also refs 11, 14, 15). The *Hha*I site in the *lac* regulatory region lies immediately after the TGA stop signal at the end of the *lac* I gene<sup>2</sup>. The *Hha*I site in exon 1 is the one used to construct the *lac*-ovalbumin in fused sequence in pOMP2 (refs 8, 18). *b*, Map of the plasmids pOMP2, pOMP21 and pOMP23, pOMP2 and its related plasmids have 32 *Hha*I sites<sup>21</sup>. Only those used to excise the *lac*-ovalbumin sequence are shown. The construction of pOMP23 involved the following steps: 20  $\mu$ g of pOMP2 DNA were digested to completion by *Hha*I (Biolabs; 25 units; 30 min at 37 °C) and the reaction was stopped by heating to 65 °C for 10 min in the presence of 10 mM EDTA. The reaction mixture was loaded on a 5–20% sucrose gradient (w/v in 25 mM Na acetate, pH 6.0, 10 mM EDTA, 0.5% SDS) and centrifuged at 31,000 r.p.m. for 16 h at 20 °C in a SW41 rotor of a Beckman ultracentrifuge. The 2.67-kilobase fragment carrying the fused *lac*-ovalbumin sequence could thus be purified from the other, much smaller fragments of pOMP2. pBR322 (ref. 21) DNA (20  $\mu$ g) was partially digested by *Hha*I. Enough enzyme was added to convert about half of the supercoils into linear molecules, which were purified by centrifugation through a 5–20% sucrose gradient (w/v in 10 mM Tris-HCl, pH 8.0, 100 mM NaCl, 1 mM EDTA; 4 h at 40,000 r.p.m. and 20 °C in a SW41 Beckman rotor). 200 ng of the 2.67-kilobase *lac*-ovalbumin *Hha*I fragment and 150 ng of linearised pBR322 were ligated with T4 DNA ligase at 4 °C in a final volume of 5  $\mu$ l in 40 mM Tris, pH 7.5, 10 mM MgCl<sub>2</sub>, 10 mM dithiothreitol, 0.1 mM ATP, 0.05 mg ml<sup>-1</sup> bovine serum albumin. After transformation of CaCl<sub>2</sub>-treated lysogenic cells of strain 1398 (ref. 22), transformants were selected on ampicillin-containing plates (20  $\mu$ g ml<sup>-1</sup>) and screened by *in situ* hybridisation<sup>23</sup> with a <sup>32</sup>P-labelled probe specific for the ovalbumin sequence (the *Hha*ov probe<sup>7,8</sup>). Positive colonies were then tested for ovalbumin production in the same radioimmunoassay as before<sup>18</sup>. All the clones positive in *in situ* hybridisation were also positive in this assay. Plasmid pOMP21 was arbitrarily chosen for further studies, and transferred into the non-lysogenic strain C600rk<sup>-</sup>mk<sup>+</sup>. pOMP21 (5  $\mu$ g) was then digested by *Sst*I (BRL, 2.5 h at 37 °C) and centrifuged in a 5–20% sucrose gradient (v/v in 10 mM Tris-HCl, pH 7.4; 20 mM NaCl; 1 mM EDTA; 45,000 r.p.m. for 140 min at 20 °C in a SW 50.1 Beckman rotor). The 6.65-kilobase fragment was treated with calf intestine alkaline phosphatase<sup>23</sup>; of this, 133 ng was ligated by T4 DNA ligase in a final volume of 5  $\mu$ l, with 100 ng of the 1.61-kilobase fragment released after digestion by *Sst*I of pBR322 carrying the *Eco*RI 'b' fragment of the ovalbumin gene. After transformation of C600rk<sup>-</sup>mk<sup>+</sup>, 12 ampicillin-resistant clones were analysed. Purified clear lysates were treated by *Hha*I and examined for the presence of the 3.9-kilobase fragment containing introns B, C and D. In such clones, the orientation of the integrated 1.61-kilobase fragment was determined by digestion with *Pst*I and *Hha*I. The unique *Pst*I site in the ovalbumin sequence lies at nucleotide 477 in exon 4 close to one end of the integrated fragment. In such analyses, plasmid pOMP23 yielded fragments of 2.13 and 1.78 kilobases (instead of 0.19 and 3.72 kilobases in the reverse orientation), demonstrating proper orientation of introns B, C and D. More precise mapping of plasmids pOMP21 and pOMP23 was achieved by the use of *Pst*I, *Bam*HI and *Sac*I. It indicated that the *lac*-ovalbumin fused sequence was most probably integrated into the *Hha*I site located at nucleotide 2,351 of the pBR322 sequence<sup>24</sup>. Replacement of the 1,612-base pair fragment of pOMP23 by the 378-base pair ov ds cDNA segment was carried out by the same procedures as above, except that *Sac*I was used instead of its isoschizomer *Sst*I (ref. 25). The letters S, P, E, B, H and Hh refer to *Sst*I, *Pst*I, *Eco*RI, *Bam*HI, *Hind*III and *Hha*I sites, respectively.

# BARR & STROUD YOUR DIRECT LINE TO THE WORLD'S FINEST LASER EQUIPMENT.

Our experience in research, development and production in the high technology areas of electro-optics ensures that we are experienced and effective in bringing you the products of some of the leading U.S. laser equipment manufacturers.

The product list includes Helium-Neon and Nd:Yag lasers, optics and coatings, micropositioning equipment, laser safety goggles, power meters and flash lamps. Our suppliers are Hughes Aircraft Company, Quantronix Corporation, Glendale Optical Company, Ardel Kinamatic, Kemlite, Laser Precision Corporation and Laser Energy Inc. An impressive line-up.

Not only do we supply this first class equipment but we complete our catalogue with lasers from our own capability. The pulsed Ruby System LU9 and the new Argon System LU15 are two examples of lasers to meet your requirements for all manner of experimental or production operations.

It is sound sense to come to Barr & Stroud for all your laser requirements. We talk your language and understand your problems. We will do everything in our power to keep you beaming.

Use the journal reply system or contact us direct for our laser catalogue.

## **Barr & Stroud** adds to your resources

## Our new $\beta$ -Endorphin RIA Kit...

will almost surely yield more sensitive, more reproducible measurements than you can get with components you prepare yourself. And without qualification we can guarantee that it will save you time and trouble.

To achieve the sensitivity we developed an antiserum which makes possible the determination of  $\beta$ -endorphin levels in the femtomole range. To assure reproducibility we screen each new component batch for compatibility with the existing components, and before shipment we run a complete assay with each lot of kits.

The resulting curve is included with your kit.

Altogether the kit is a complete system, designed to save you the time and trouble it takes to develop a good antiserum, purify the tracer, match the components, and maintain everything. One kit contains reagents for performing 250 assays.

Find out more. Send for our brochure describing the kit and assay procedure.

### PRA's new arc lamp systems. More power at less cost per watt.

- 2 to 6 times more useable power for given lamps over conventional systems
- Water cooled
- Sealed to significantly reduce ozone health hazard
- Designed to allow direct imaging into monochromators without the use of lenses
- Allows for use of lower-powered lamps for Reduced Operating Cost

The regulated power supplies are:

- Modulatable up to 25 KHZ
- Pulsed mode operation and optical feedback capability
- Highly regulated — 0.1% ripple under full load
- Low RF, filtered single pulse starters

The supplies can power most arc lamps from 75W — 1000W.

**Fig. 2** Synthesis of ovalbumin-like protein by pOMP21 and pOMP23. C600rk<sup>+</sup>mk<sup>+</sup> (pOMP21) and C600rk<sup>+</sup>mk<sup>+</sup> (pOMP23) were grown overnight in L broth supplemented with 20  $\mu\text{g ml}^{-1}$  ampicillin, diluted into fresh medium containing 1 mM isopropylthiogalactoside, grown to about  $4 \times 10^8$  cells per ml, concentrated about 100-fold, and sonicated twice for 30 s as before<sup>18</sup>. The procedures for iodination of ovalbumin, purification of antibodies and radioimmunoassays have been described previously<sup>18</sup>. In the experiment shown, the dilution of antiserum chosen was able to precipitate 30% of the iodinated ovalbumin ( $B_0$ ). Results are expressed as  $B/B_0$ , the ratio between the c.p.m. precipitated in the presence or the absence of competing material (blanks being subtracted each time).  $B$  was measured in duplicate and  $B_0$  was the average of four determinations. ○, Results obtained with pure ovalbumin; ●, those obtained with pOMP21, representing the synthesis of about 6,500 molecules per bacterium. ●, Results obtained with pOMP23. Similar results are obtained in various hosts. C600rk<sup>+</sup>mk<sup>+</sup> carries the *supE* suppressor for amber mutations.

by K. O'Hare *et al.* (personal communication), and where the sequence of the various exons matched those of *ov* mRNA. It thus seems unlikely that inadvertent mutations cause the defect in expression of the ovalbumin-like product. Instead, we conclude that the introduction of introns *B*, *C* and *D* in the fused *lac*-ovalbumin sequence blocks the expression of ovalbumin-like product in *E. coli*.

The sequence data of K. O'Hare *et al.* indicate that introns *B* and *C* are 252 and 582 base pairs long (84 and 194 triplets, respectively) so that their presence will not alter the reading frame. In contrast, intron *D* consists of 401 base pairs (133 triplets plus 2 base pairs) and will cause a frameshift. (The sequence data of Robertson *et al.*<sup>28</sup>, obtained with another cloned DNA, show some differences; in their case, intron *C* would also cause a frameshift.) Further, intron *B* contains one nonsense codon (TGA), intron *C* shows 12 nonsense codons (four TAA, three TGA and five TAG) and intron *D* contains three TGA and three TAA stop signals. All these nonsense codons are in the same reading frame, and although the bacterial host used had some suppressing capabilities (see legend to Fig. 2) it is unlikely that efficient suppression could occur. Because, in addition, intron *D* causes a frameshift, any synthesis of ovalbumin-like product in *E. coli* would probably result from the splicing of intron sequences from the primary RNA transcript. The mechanisms involved in RNA splicing in the higher eukaryotes are still poorly understood. It is possible that additional, unknown eukaryotic genetic elements could promote splicing in *E. coli*. Also, we cannot rule out the possibility that the simultaneous presence of the seven introns of the ovalbumin gene is a prerequisite for splicing in *E. coli*. It seems very likely, however, that splicing does not readily occur in *E. coli*, and that the isolation of split genes or the production of the corresponding proteins cannot be based at this stage on their expression in *E. coli*.

Biohazards associated with the experiments described here were examined by the French National Control Committee. We thank Dr P. Chambon, K. O'Hare, C. Benoist and R. Breathnach for communicating unpublished results (especially sequence data) and for interesting discussion, Dr F. Rougeon for enzymes, Mrs O. Le Bail for technical help and Professor Fauve for the use of his  $\gamma$  counter. This work was supported by grants from CNRS (ERA No. 201 and ATP No. 3558), INSERM (CRAT No. 76.4.310 and 76.4.465), FRMF and DGRST.

## About 30% of minute virus of mice RNA is spliced out following polyadenylation

MANY viral and eukaryotic messenger RNAs have been shown to contain blocks of sequence which, although adjacent to one another in the RNA, are copied from non-contiguous regions of the genome that are joined together post-transcriptionally. This phenomenon of RNA splicing has been shown to occur during the processing of several DNA and RNA tumour viruses<sup>1-7</sup> and cellular<sup>8-10</sup> mRNAs. The mechanism by which splicing is carried out has not been elucidated, and any direct approach is complicated by the elaborate splicing patterns found in the systems which have been examined so far. We have extended these studies of RNA splicing to a potentially simpler viral system, the minute virus of mice (MVM), a non-defective member of the parvovirus group. The members of this group are considered to be among the simplest of the animal viruses, and comprise an icosahedral virion made from three structural protein species, containing one linear single-stranded DNA chromosome of  $\sim 1.5 \times 10^6$  molecular weight (for review see ref. 11). The MVM DNA molecule contains a stable hairpin duplex at its 5'-end and a 3'-terminal structure suitable for priming complementary strand synthesis *in vitro*<sup>12,13</sup>. Little is known about the transcription process in parvoviruses. The only cytoplasmic mRNA species found for adeno-associated virus (AAV), a member of the defective subgroup, is a transcript of 70% of the genome which has been shown by *in vitro* translation to code for the three capsid proteins<sup>14</sup>. The one study of transcription carried out in the non-defective subgroup has identified an analogous RNA species in Kilham rat virus (KRV)-infected cell cytoplasm which is complementary to 70% of the viral strand and sediments as a single component at about 18S (ref. 15). We report here our attempts to determine the sequence arrangement of MVM RNA by examining, in the electron microscope, hybrids formed between the abundant species of nuclear and cytoplasmic poly(A)<sup>+</sup> RNA and single-stranded genomic DNA. We have found that about 30% of MVM RNA is spliced out following polyadenylation.

**Fig. 1** Electron micrographs and their tracings of hybrids formed between nuclear poly(A)<sup>+</sup> RNA and MVM DNA. A-9 cells, a derivative of the mouse L-cell line ( $3 \times 10^7$  cells) were infected with 1–2 plaque-forming units per cell of plaque-purified strain T of MVM. At 20 h p.i., nuclear and cytoplasmic fractions were prepared<sup>18</sup>, and RNA extracted<sup>19</sup> and fractionated on oligo(dT) cellulose columns to poly(A)<sup>+</sup> and poly(A)<sup>−</sup> molecules. Genomic single-stranded DNA was extracted from purified virions<sup>12</sup>. The RNA was precipitated in ethanol with the genomic single-stranded DNA (0.5  $\mu$ g). The pellet was collected by centrifugation and resuspended in 66% (v/v) of repurified formamide, 3 M urea, 20 mM EDTA and 0.2 M Tricine-NaOH, pH 8.1. The hybridisation mixture was incubated at 37 °C for 6 h. Samples were prepared for visualisation in the electron microscope as detailed by Bratosin *et al.*<sup>22</sup>. Scale bar, 0.5  $\mu$ m.

Hybrids were obtained by annealing poly(A)<sup>+</sup> nuclear RNA and MVM genomic DNA. Figure 1 shows the appearance of representative RNA–DNA structures with their schematic tracings. Molecules of unit length MVM DNA were selected and examined for single- and double-stranded regions. Of more than 100 molecules scored, at least 95% exhibited double-stranded appearance over the entire length of the DNA. It should be emphasised, however, that the present analysis would not detect single-stranded regions of less than 50 nucleotides. Each hybrid examined shows a short Y-shaped structure at one end, consisting of one double-stranded and one single-stranded arm. The lengths of the two arms support the assumption that the double-stranded arm is the 130-base pair hairpin known to be at the 5'-end of the viral DNA<sup>12</sup> and that the single-stranded arm represents at least in part the poly(A) on the 3'-end of the RNA. The opposite end of these hybrid structures exhibit, in 50% of molecules examined, a short single-stranded region of up to 150 nucleotides, suggesting that the initiation of transcription might occur in a number of alternative sites. In this context it is noteworthy that SV40 nuclear and cytoplasmic RNAs have various 5'-terminal sequences<sup>20,21</sup>. As the complete (or almost complete) double-stranded hybrids formed with nuclear RNA are by far the most abundant structures observed in the electron microscope, it seems that poly(A)<sup>+</sup> nuclear RNA is a complete (or almost complete) transcript of the genomic DNA, and suggests that it is the precursor for cytoplasmic poly(A)<sup>+</sup> mRNA. Moreover, because the template for transcription is at least in part a linear DNA molecule (unpublished results), we conclude that transcription is always initiated within a region located at the extreme 3'-end of the viral chromosome. This correlates well with the proposed structure of the nuclear precursor for the AAV messenger RNA<sup>14</sup>.

RNA was extracted from the cytoplasmic fraction of MVM-infected cells at 20 h post-infection (p.i.). Poly(A)<sup>+</sup> RNA was selected by chromatography on oligo(dT) cellulose columns. About 25% of <sup>3</sup>H-uridine-labelled poly(A)<sup>+</sup> cytoplasmic RNA (labelled 16–20 h p.i.) hybridised with genomic DNA, indicating

that the viral RNA comprises a substantial fraction of the poly(A)<sup>+</sup> RNA present in the infected cells.

Hybrids were obtained by annealing the poly(A)<sup>+</sup> cytoplasmic RNA and MVM genomic DNA. Figure 2 shows the appearance of representative RNA–DNA structures with their schematic tracings. As in the analysis of nuclear RNA, hybrids containing unit length MVM DNA were selected and examined for single- and double-stranded regions. Of about 100 molecules scored, more than 85% exhibited one short and one long arm of duplex with an intervening single-stranded DNA loop. As with the hybrids containing nuclear RNA, one end, that of the long duplex arm, has a short Y-structure comprising one double strand and one single strand, which we again postulate is the 3'-end of the RNA. As with the nuclear RNA–DNA hybrids, the opposite end, that of the shorter duplex arm, exhibited a short single-stranded region in many of the molecules examined. The observation made with the nuclear and cytoplasmic poly(A)<sup>+</sup> viral RNAs suggests that the MVM poly(A)<sup>+</sup> cytoplasmic RNA is a spliced molecule composed of two parts: a short 'leader' and a longer 'body'. The single-stranded DNA loop (see Fig. 2) contains the intervening template for RNA sequences which are present in the nuclear poly(A)<sup>+</sup> RNA and have been spliced out in the cytoplasmic poly(A)<sup>+</sup> RNA. The analysis of nuclear and cytoplasmic RNAs also indicates that the sequence of modifications during mRNA maturation is polyadenylation followed by splicing. We have measured the three parts on the RNA–DNA structures shown in Fig. 2 and the results of these measurements are presented in Fig. 3. Sharp histograms were obtained for each of the three parts: the leader spans  $8.8 \pm 1.2\%$  of the structure, the single-stranded DNA loop (or intron) spans  $29.3 \pm 2.4\%$  of the structure and the body spans  $61.8 \pm 2.3\%$  of the structure. The map coordinates of each part of the structures are represented in Fig. 3b.

The present study does not indicate whether the poly(A)<sup>+</sup> cytoplasmic RNA which we have analysed is the only viral RNA present in the infected cells. However, if there are other RNA species coded for by the viral strand, its abundance should be less than 15% of this species. Similar analysis of poly(A)<sup>−</sup> RNA from infected cells revealed only a minor fraction of short heterogeneous RNA–DNA hybrids, with no accumulation of any particular length.

It is thought that the MVM genome has a small number of structural genes, perhaps only one<sup>16</sup>. The coding capacities of

**Fig. 2** Electron micrographs and their tracings of hybrids formed between cytoplasmic poly(A)<sup>+</sup> RNA and MVM DNA. Cytoplasmic poly(A)<sup>+</sup> RNA was prepared, annealed with genomic DNA and visualised in the electron microscope as detailed in Fig. 1. Scale bar, 0.5  $\mu$ m.

**Fig. 3** *a*, Histograms of the leader, intron and body obtained from analysing structures as shown in Fig. 2. One map unit (MU) corresponds to 1% of the length of the entire structure. *b* Shows the coordinates of each part on the viral DNA. The 3'- and 5'-ends of the genomic DNA were taken as 0 and 100 MU, respectively. Leader,  $8.8 \pm 1.2$  MU; spliced out,  $29.3 \pm 2.4$  MU; body,  $61.8 \pm 2.3$  MU.

the leader and body of the poly(A)<sup>+</sup> RNA are about 12,000 and 90,000 daltons, respectively. If only the body codes for polypeptides, as in adenovirus<sup>1</sup> and SV40 late mRNAs<sup>2</sup>, then it could code for polypeptide A (83,000 daltons) and protein B would be processed from this. If this is true then the viral mRNA would represent only about 70% of the viral genome and its primary transcript. Elucidation of the role of the remaining 30% of the primary transcript would be of great interest.

It is possible, however, that the MVM genome contains several genes, as a result of more than one functional initiation or termination site during translation. In this respect, it is noteworthy that splicing of RNA sequences at the post-transcriptional level could give rise to several functional mRNAs from the same precursor RNA, as has been found for SV40 early mRNAs<sup>17</sup>. These mRNAs could be translated in the same reading frame or switched from frame to frame.

The splicing of MVM RNA described in the present study resembles that of the mRNAs of other viruses and of eukaryotic cells but seems to be considerably less complex. Therefore, the transcription and processing of parvovirus mRNA provides a very useful model system for studying the mechanism of splicing and the physiological significance of this novel process in animal cells.

This research was supported in part by the Israeli Cancer Association and in part by the NCI. J.T. thanks the International Union Against Cancer for a travel fellowship.

## RNA polymerase unwinds an 11-base pair segment of a phage T7 promoter

WHEN RNA polymerase binds to a promoter site, it must unwind part of the DNA double helix so as to expose the template bases. Wang *et al.*<sup>1</sup>, Melnikova *et al.*<sup>2</sup> and Hsieh and Wang<sup>3</sup> have used different experimental techniques to measure the degree of unwinding. Their estimates range from 7 (ref. 1) to 15 (ref. 2) base pairs unwound per bound *Escherichia coli* RNA polymerase (EC 2.7.7.6). These studies, however, do not establish which part of a promoter is melted out. A new technique described here directly proves unwinding and furthermore identifies the exact region that RNA polymerase opens in the A3 promoter of phage T7. This promoter is one of three strong *E. coli* RNA polymerase promoters used early in the life cycle of phage T7 (ref. 4).

Dimethyl sulphate (DMS) methylates the N-7 position of G and the N-3 of A on double-stranded DNA<sup>5</sup>. On single-stranded DNA, however, the N-1 of A and to a much lesser extent, the N-3 of C can also be methylated<sup>5</sup>; these positions are not accessible on double-stranded DNA because they are involved in hydrogen bonding (Fig. 1).

My technique takes advantage of this difference between single and double stranded DNA. First, I isolate the promoter on a restriction fragment which carries a <sup>32</sup>P label on the 5'-end of one strand only<sup>6</sup>. Then a complex between RNA polymerase holoenzyme and this promoter fragment is exposed to DMS. Wherever the RNA polymerase has unwound the double-stranded DNA, the N-1 position of A can be methylated. Precipitation of the DNA removes the RNA polymerase, allowing the two DNA strands to renature, except where the N-1 of A is methylated. The single strand-specific nuclease, S<sub>1</sub>, which cuts at unpaired bases<sup>7</sup>, will cut the DNA strand at mismatched A

**Fig. 1** AT base pair showing sites of methylation (see text).

and T bases created by methylation. This generates labelled strands, which terminate at the  $S_1$  cutting sites. When the  $S_1$  products are electrophoresed on a denaturing polyacrylamide gel<sup>6</sup> next to the sequence of the labelled strand, the lengths of the labelled  $S_1$ -cleaved strands identify the base pairs which were originally melted out by RNA polymerase.

Figure 2 shows an autoradiogram of such an experiment. The promoter fragment is an *HhaI*-*AluI* fragment of phage T7, carrying the A3 promoter, with transcription proceeding towards the *AluI* end<sup>4</sup>. As the *HhaI* end was labelled, Fig. 2 shows the  $S_1$  cuts on the sense strand. Due to the 3'-overhang at

**Fig. 2** Autoradiogram of a 12% polyacrylamide, 7 M urea gel<sup>6</sup> with the  $S_1$  nuclease digest of the A3 promoter fragment, which was previously methylated while complexed with RNA polymerase, in lane (R+S+). In the control lanes either  $S_1$  (R+S-) or RNA polymerase (R-S+) or both  $S_1$  and RNA polymerase (R-S-) were left out of the otherwise identical procedure. In another control, the DMS methylation was omitted from the protocol and again no  $S_1$  cleavage was observed (not shown here). The G/A lane represents the sequence of the fragment according to the 'G greater than A' method of Maxam and Gilbert<sup>6</sup>. The numbers indicate positions of the promoter sequence (see Fig. 3). A 0.5–1- $\mu$ g sample of the 155-base pair long *HhaI*-*AluI* fragment was preincubated with 9–10  $\mu$ g of RNA polymerase holoenzyme (greater than 90% saturation with the  $\sigma$  subunit) in 100  $\mu$ l of binding buffer (0.01 M  $MgCl_2$ , 0.1 mM EDTA, 1 mM dithiothreitol, 50 mM Na cacodylate pH 7.3, 0.05 M KCl) for 1–2 min at 37 °C. Then 3–4  $\mu$ l of a 10.4 M DMS solution were slowly added during the reaction, which was quenched (see ref. 6) after 3 min by adding 100  $\mu$ l of 1 M mercaptoethanol, 1% SDS and 2 M  $NH_4$  acetate, pH 5 (acidic conditions stabilise the labile N-1-methyl of A (ref. 5)). After precipitation with 2.5 volumes ethanol, the DNA was digested with approximately 4 units of  $S_1$  nuclease in 50  $\mu$ l of  $S_1$  buffer<sup>8</sup> (0.03 M Na acetate, pH 4.6, 0.05 M NaCl, 1 mM  $ZnSO_4$ , 5% glycerol) for 1 min at 37 °C. The reaction was stopped with EDTA and SDS.

**Fig. 3** A3 promoter sequence<sup>4</sup>. The canonical sequences<sup>4</sup> of the Pribnow box and the -35 region homologies, the initiation site and the unwound region are shown.

the *HhaI* site, the 5'-label here should not be accessible to  $S_1$  attack; nonetheless, about 25% of the counts cannot be precipitated after  $S_1$  incubation, which may reflect 'breathing' of the ends.

The experiment in Fig. 2 visualises the unwound region in lane (R+S+) and shows it to be an 11-base pair segment extending from about the middle of the Pribnow box, a region of strong promoter homology<sup>4</sup>, to just past the initiation site (Fig. 3). The same limits appear in the analogous experiment with the antisense strand (labelled at the *AluI* end) (data not shown). This proves that there was no significant nibbling back by  $S_1$  at the nicks, as that would shorten the size of the  $S_1$ -cleaved strands and, therefore, shift the limits for unwinding towards the 5'-labels of either strand. The blurring of the bands is probably due to extensive methylation which will insert extra positive charges.

$S_1$  cuts appear at almost every position of the unwound region (except around the two successive CG base pairs). Most probably, the limited  $S_1$  digestion causes cuts at either 5'- or 3'-side of a mismatched A or T, generating two labelled strand fragments which are separated by one nucleotide. This would account for  $S_1$ -cleaved strands migrating with Cs or Gs of the sequence; no significant methylation at the N-3 of C need have occurred. (Due to the 3'-OH end of  $S_1$ -cleaved strand fragments<sup>8</sup>, they will migrate slightly more slowly than the corresponding sequence strand fragment, which ends in 3'P (ref. 9).)

The unwound region I detect represents a minimum sequence, because if RNA polymerase were very tightly associated with the N-1 of an A: for example, it would prevent the methylation of that position and consequently the detection of such a melted base pair. Also, the CG base pairs bounding the unwound region may or may not have been opened.

The experiment directly shows that RNA polymerase unwinds a region covering 11 base pairs of the A3 promoter. This agrees well with previous estimates<sup>1-3</sup>. The unwound region includes the initiation site and, more surprisingly, the latter half of the Pribnow box homology, suggesting that the Pribnow box may serve to initiate unwinding. I have probed for specific contacts between the A3 promoter and the polymerase with DMS and ethylnitrosourea according to techniques developed by Gilbert *et al.* (ref. 10 and unpublished data). Almost all contacts identified lie upstream from the unwound region (unpublished).

The new technique described here can detect any transiently opened AT base pairs; it should be useful in determining whether certain enzymes unwind DNA and, if so, which segments of the DNA they unwind.

I thank Walter Gilbert for advice and for help with the manuscript. This work was supported by an NIH grant (GM 09541-17) to Walter Gilbert.

# ENERGY SCIENCE and TECHNOLOGY

A Series of Graduate Textbooks, Monographs, Research Papers

## ENERGY CONVERSION ENGINEERING

**Richard C. Bailie**, West Virginia University and Environmental Energy Engineering, Inc. Morgantown, West Virginia

**From the Editors' Foreword**—"The first volume of the new ENERGY SCIENCE AND TECHNOLOGY SERIES, presents the fundamental background material needed to understand the basic principles involved in energy conversion systems. The book also serves as an introduction to much of the material that will be appearing in subsequent volumes of the Series. In addition, 'Energy Conversion Engineering' provides an excellent review for scientists and engineers who are either entering into or redirecting their activities to the area of energy science and technology."

**Contents:** Energy Uses and Resources, Thermodynamics, Chemical Reaction Equilibrium and Kinetics, Combustion of Fossil Fuel for Heat and Power, Coal Gasification and Liquefaction, Nuclear Energy, Solar Energy, Environmental Considerations, Economics, Politics and Social Implications, Appendices and Index.

1978, 556 pp., illus. Hardbound 00840 \$19.50

The Second Volume in the Series . . .

## COAL CONVERSION TECHNOLOGY

**C. Y. Wen and E. Stanley Lee** (eds.)

During the remainder of this century and well into the next, coal will be utilized in many different ways to replace present usage of oil and gas. Technological advances are currently demonstrating that coal may be converted into other useful energy forms in addition to electricity and metallurgical coke.

This multi-contributor volume critically reviews and presents reliable information in the areas of coal combustion, gasification, and liquefaction. It is written for scientists and engineers working in this area, as well as for advanced undergraduate and graduate-level courses.

**Contents:** COAL CLASSIFICATION AND CHARACTERIZATION, S. Ergun, RATE OF COAL PYROLYSIS AND GASIFICATION REACTIONS, C. Y. Wen and S. Dutta, COAL COMBUSTION, Robert H. Essenhigh, COAL GASIFICATION, L. G. Massey, COAL LIQUEFACTION, E. Stanley Lee, References and Index.

1979, Hardbound 08300, in preparation  
Continuation orders are invited.

## ENERGY

### A Three-Volume Set of Lecture Notes

"This reviewer knows of no comparably complete collection of data on energy demand, production, and projection problems and policies, and would recommend it for serious consideration as a text for a contemporary energy course (there is substantially more material here than could be included in less than a full-year course) or simply as a convenient reference source for all those involved or interested in current energy problems."

## Analytical history of ornament

N. K. Humphrey

*The Sense of Order: A Study in the Psychology of Decorative Art.* By E. H. Gombrich. Pp. 411. (Phaidon: Oxford, 1979.) £15.

*The Psychology of Decorative Art* is the title of a book which has still to be written. That Gombrich should have used it as the sub-title of his latest essay in *Art History* is a pity for two reasons: first because it will mislead the reader as to what the book is really about; and second, because it has apparently misled the author into biting off more than he can chew. Despite its pretensions this book has very little of value to say about psychology. It has, however, a great deal to say about the more traditional subject matter of the art historian: craftsmanship, style, symbolism, tradition, patronage, and especially about what other critics have had to say about these things.

The body of the book is an analytical history of ornament. From time immemorial *homo faber*—man the serious-minded maker of useful artefacts—has openly cohabited with a more flippant mistress: where he might otherwise have been content with objects which were merely functional, she, his playful (and sometimes tiresome) muse, has persuaded him to decorate them. Her nature, it seems, abhors a visual vacuum; wherever she sees an empty surface, a hard edge, a simple corner, she yearns to overlay it or surround it with decorative patterns. So floors and walls are covered with geometrical designs; an arabesque runs around the cooking pot; the hilt of a sword is decked with jewels; stone columns are fluted and topped with a wreath of acanthus leaves; even the letters of the alphabet are adorned with knots and flourishes.

Gombrich brings to bear on these and related examples of human eccentricity his unrivalled combination of erudition, curiosity and taste. The first chapters deal with the criticism of ornament, the cult of purity and the debates about design in Victorian England. Next the craftsman's practice of pattern making is discussed as a response to the challenges of material, of geometrical laws and visual constraints. And, in perhaps the most intriguing sections of the book, the origins and fate of certain traditional motifs are followed through (the Paisley pattern,

the acanthus scroll, and others). An Epilogue reviews some of the analogies between the spatial orders of decorative design and the temporal patterns of the dance, of poetry and, notably, of music.

Amidst all this there is, let it be said, a sprinkling of psychology, or what might less kindly be called 'psychologising'. Reference is made (particularly in three middle chapters) to 'gestalt formation', 'selective attention', 'information theory', and so forth. But—and I do not think it is merely the closed-shop mentality of a professional psychologist which makes me say it—I found these excursions into experimental psychology for the most part trite, irrelevant or amateur. Although no-one has yet made a good job of linking art and psychology, Gombrich himself in his earlier book, *Art and Illusion*, has already made a much better job of it than he does here.

To the reader looking for a psychological explanation of design, however, the biggest disappointment will come with the vacuity of the 'biological' arguments which Gombrich propounds at the beginning of the book. It may be true that man and other animals have an innate 'sense of order', and that they find order relaxing and a mild

degree of disorder interesting (*ergo* pleasurable?). But Gombrich does not present a convincing case for why this should be so; nor, having set out the thesis, does he draw any but the most banal conclusion from it—that people like what we already know they like. For me at least, it adds nothing to the understanding of man's love of order to point out that "Nature around us is throbbing with complex rhythms, and these rhythms serve the purpose of life". True, man's heartbeat is rhythmical, and he would be dead if it were not; but, equally, his blood is red and he would be dead if it were not—and that surely does not explain why he prefers the colour red to blue.

The book is finely illustrated, and, as always, Gombrich proves a brilliant guide as to what to see and why. I shall never look at the roof of King's Chapel, or a William Morris wallpaper or a Paisley pattern tie in quite the same way again. But the way in which Gombrich succeeds in deepening our perception of these patterns is by telling us more about their makers rather than by telling us more about ourselves. □

N. K. Humphrey is Assistant Director of Research at the Sub-Department of Animal Behaviour, University of Cambridge, UK.

# Disaster strikes from the blue

Peter J. Smith

*Earthshock.* By Basil Booth and Frank Fitch. Pp. 257. (Dent: London, Toronto and Melbourne; Walker: New York, 1979.) Hardback £6.95, \$11.95; paperback available from Sphere (London) in May, 1980.

WITHIN ten minutes of taking up this book I had come to two conclusions, both minor in themselves but both, it subsequently became clear, indicative of deeper malaise. The first was that someone has seen fit to impose a veneer of silly sensationalism on an already spectacular topic, presumably in the belief that a bit of spurious exaggeration does little harm to sales. It begins with the title. An earthshock, it seems, is simply a natural disaster. A short snappy title is all very well, and even to be applauded, but not at the expense of accuracy. As not all natural disasters (for example, glaciation) can be remotely regarded as "shocks", the authors are reduced to referring to "slow earthshocks", which reminds me of that superb character of childhood rhyme, the "bare-footed man with clogs on [who] came slowly running past".

Then there is the lurid dust jacket, showing a huge "tidal wave" about to overwhelm a Manhattan-style environment. Well, all right. More importantly, however, there is the jacket blurb which asks, "can the Earth survive?" and asserts that "A single great natural disaster . . . could destroy civilisation as we know it". For a start, no-one outside Monty Python refers any more to "civilisation as we know it", at least not without inviting ridicule. Yet the basic fault here is not some blurb-writer's exuberance but the authors, who adopt the same tone in parts of the text. They begin the book, for example, with a crude five-page account of the destruction (in 1987) of America's eastern seaboard by a fireball and its aftermath, and subsequently discuss nation-scale disaster from a serious scientific point of view. Is it worth spending time thinking about such unlikely (but admittedly possible) catastrophes when we cannot even cope adequately with events that are more familiar?

The second conclusion is that the book contains far too many flow-stoppers, ranging from the trivial to the more serious. The Earth's crust, mantle and core are referred to throughout somewhat eccentrically as

Crust, Mantle and Core. "Dilatancy" has become "dilateness". "Pangaea" appears as "Pangea"—a perfectly acceptable, indeed desirable, simplification in the context of the abolition of all ligatured diphthongs and their remnants, but presumably a mistake in a book that refers to aeolian, Palaeozoic and palaeomagnetism (and even, in one place, the idiosyncratic "palaeomagnetic"). Imperial units (feet, miles, and so on) are used throughout without even the parenthetical acknowledgement of metric units—a disgrace when (outside North America) a whole generation of children has been brought up on metric units. And even more seriously, one is continually being brought up sharply by the almost impenetrable: "However academic the study of plate movement may seem, its importance cannot be minimised". What does this mean?—the very opposite of what it actually says?

If that were the sole extent of the problem I could perhaps be accused of nit-picking. Unfortunately, however, the confusion goes much deeper, ruining some good ideas in the process. For example, before tackling natural disasters as such, Booth and Fitch devote some 50 or so pages to spelling out the nature of the generally more gradual processes involved in the Earth's behaviour. This is an excellent approach. All too often the authors of "popular" books on natural hazards give the impression that disaster strikes from the blue with little, if any, reference to the context in which terrestrial events and processes can combine to produce catastrophe. But to cover this background in so short a space is difficult and needs careful planning. Booth and Fitch do not entirely succeed. This section is rather confused, dense in concepts and terms all too frequently inadequately explained, and thus likely to be hard going for the non-expert.

The remainder of the book is devoted largely to particular natural hazards—to their general characteristics and to specific examples of disasters they have generated. Here the going is easier. To me, these chapters become more and more engrossing as the material becomes less and less familiar during the progression from earthquakes, through volcanoes, glaciation and flooding to extraterrestrial bombardment. But individual readers will have their own interests. To be objective about it, the book is probably most authoritative on those topics—especially volcanic matters—closest to the authors' hearts. On subjects closer to my heart, on the other hand, respect for the facts is not always all it should be. The notorious Denver earthquakes of the 1960s were not noticed by US

Geological Survey scientists in 1966 but by the alarmed inhabitants of Denver some years before; and the cause of the shocks was discovered by David Evans, a consultant geologist, in 1965. Moreover, the cause was not the injection into the ground of "industrial" waste fluids but of military waste material. The emotional overtones of the affair were thus rather different.

Some of the authors' judgements are also questionable. To say, as Booth and Fitch do, that "If the scientists involved in this work [that is, earthquake studies] are given sufficient encouragement and adequate financial support there is no reason why earthquake prediction should not become a routine matter within a decade" is really far too optimistic and therefore grossly misleading to the uninitiated. Indeed, it seems an unlikely prognosis even in respect of geologically comparatively simple areas such as the San Andreas fault zone of California. Moreover, to give the impression that prediction is purely or even primarily a scientific problem is dangerous. The social implications of a viable earthquake prediction capability are so complex that there must be real doubt whether non-totalitarian régimes could cope adequately with such a power without significant, and perhaps unacceptable, changes in socio-political attitudes.

Failure to give adequate attention to such factors is to demonstrate political naivety, a condition not uncommon among academic scientists. It is also naive to suggest, as Booth and Fitch do, that "the United Nations should have a single, comprehensive world natural disaster control agency with certain overriding powers, able to investigate and prepare for all types of natural disaster anywhere in the world, ready to go in with the right kind of advice and aid immediately it is required, without political let or hindrance". The United Nations has been conspicuously unsuccessful in almost everything it has ever tried to do precisely because such supranational authority is totally unacceptable to any nation of any consequence; and perhaps there is some merit in that uncooperative attitude when one takes account of the motives of the supranationalists. As Booth and Fitch put it, "people must be prevented from falling victim to their own or other people's stupidity and avarice by strictly enforced laws". Nasty.

Despite its descriptive merits, the long-awaited *Earthshock* is at best a disappointment and at worst a bit of a disaster. □

THE THIRD EDITION

Kirk-Othmer

## ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY

Editorial Board:

Herman F. Mark, *Polytechnic Institute of New York*;  
Donald F. Othmer, *Polytechnic Institute of New York*;  
Charles G. Overberger, *University of Michigan*;  
Glenn T. Seaborg, *University of California, Berkeley*.

Executive Editor: M. Grayson Associate Editor: D. Eckroth

The Encyclopedia will include about 1000 articles contributed by experts in various aspects of chemical technology. The articles will deal with industrial products, natural materials and related groups of substances. A major part of the Encyclopedia will review uses of products of the chemical and process industries from pharmaceuticals, dyes, herbicides and semiconductors to laser materials, coatings and membranes. The Third Edition will consist of 25 volumes, which are planned to appear at the rate of four volumes annually.

Subscription price per volume \$120.00/£60.00  
Individual volume price \$150.00/£75.00

"This new set isn't just a revision of the second edition, it's a whole new encyclopedia. . . I'm really impressed with the quality of the articles in this new edition. Kirk-Othmer has long had a reputation for being authoritative, and the new edition will indeed enhance this reputation."

Roy V. Hughson, **CHEMICAL ENGINEERING**  
October 1978

### Progress in Macrocyclic Chemistry Vol. 1

edited by R.M. Izatt and J.J. Christensen, both of Brigham Young University.

The first volume in a new series devoted to current important areas of macrocyclic chemistry. The book contains material about the new rapidly-growing field of chemistry of synthetic cyclic organic compounds (synthetic multidentate macrocyclic compounds). The authors discuss the physical and chemical properties of these molecules together with their various applications in the world of chemistry. (*Progress in Macrocyclic Chemistry Series*)

April 1979 288 pages  
0471 03477 0 \$35.75/£17.95

### Asbestos: Vol. 1: Properties, Applications and Hazards

edited by L. Michaels, *British Postgraduate Medical Federation* and S.S. Chissick, *Department of Chemistry, King's College, London*.

This two-volume work provides the first coverage of all the fundamental and essential information on asbestos.

Volume 1 covers the basic science of the material (mineralogy, chemistry and physics); its effects on the health of people exposed to it in industrial and non-industrial situations; the approaches of governments, employers and trade unions in the US and Europe to the material and its attendant hazards; the collection and identification of asbestos in solid and airborne samples; and substitute materials for general, industrial and building construction purposes.

April 1979 566 pages  
0471 99698 X \$60.00/£25.00

### Photometric and Fluorometric Methods of Analysis: Metal — Parts 1 and 2

by F.D. Snell, *Foster D. Snell Inc.*

A compilation of all recently published methods of determination for fifty-seven common and uncommon metals and the rare earths. Each chapter is a quasi-monograph on the determination of one element with references to the original literature. It reflects the recent development of instruments permitting more rapid, accurate, and economical methods.

March 1979 2192 pages  
0471 81014 2 (2 part set only) \$195.00/£98.00

### Catalytic Hydrogenation in Organic Synthesis: Procedures and Commentary

by M. Freifelder, *formerly of Abbott Laboratories*.

Based on the knowledge attained from over twenty-two years of experience this gives detailed descriptions of many experiments providing step-by-step procedures along with personal notes and observations, directions, suggestions, and safety precautions. The yields obtained in the experiments are good-to-excellent, and most of the hydrogenations discussed are carried out under mild conditions.

December 1978 208 pages  
0471 02945 9 \$24.50/£12.30

### Iminium Salts in Organic Chemistry Part 2

edited by H. Böhme, *Universität Marburg, Lahn, Germany*, and H.G. Viehe, *Université de Louvain, Belgium*.

Together, Parts 1 and 2 describe almost all aspects of the potential of iminium functions in syntheses of nature, industry and research. Part 1 (published in February 1977) covers theoretical and physical aspects. Part 2 provides more synthetically oriented chapters underlining the power of the iminium function. (*Advances in Organic Chemistry Series Vol. 9*)

April 1979 852 pages  
0471 90693 X \$90.00/£45.55

### Recent Developments in Aerosol Science

edited by D.T. Shaw, *State University of New York at Buffalo*.

Together with its companion volume, **FUNDAMENTALS OF AEROSOL SCIENCE** (published in July 1978), this book constitutes the first state-of-the-art review of recent developments in aerosol science and technology since 1966. Chapters are written by authorities representing various branches of aerosol research and each chapter is followed by an extensive bibliography.

April 1979 344 pages  
0471 02950 5 \$32.50/£16.30

### Physical Chemistry 5th Ed.

by R.A. Alberty, *Massachusetts Institute of Technology*, and F. Daniels.

*Physical Chemistry* provides clear explanations of the fundamentals of the subject; this edition has been reorganized to present quantum chemistry before chemical dynamics, so that it is possible to use quantum and statistical mechanical ideas in discussing chemical kinetics and also to discuss photochemistry in the context of kinetics.

May 1979 696 pages  
0471 02222 5 \$23.95/£11.95

# Photomacrography: easier than ever before.

## WILD M400 PHOTOMAKROSKOP.

No other photographic technique today is so reminiscent of the methods of yesteryear's pioneers in photography as is photomacrography (range 1:1 to 20:1). In the past, the bellows was unwieldy, setting the image scale complicated and calculating the exposure time a long-drawn-out operation. You literally had to grope for the object. Not what you would call efficient! And yet efficiency is just what is needed in science and technology where photomacrography is playing an ever more important role.

Now Wild Heerbrugg has developed a new photomacrographic system, the Wild M400 Photomakroskop.

Modern photographic technology and electronics guarantee a high degree of efficiency within the magnification range of 1:1 to 60:1. Magnification and detail can be continuously varied with the macrozoom objective 1:5. What's more, the M400 gives you binocular observation under **optimum physiological conditions**, an erect and laterally-correct image and a great working distance. The specimen remains in focus over the whole zoom range. The electronic control unit ensures **ideal exposure time at the touch of a button**, independently of camera format, film emulsion and illumination method. It's easier and better than ever before.

# Travelling through time

Stephen Siklos

*Time Warps*. By John Gribbin. Pp. 167. (Dent: London, Melbourne and Toronto; Delacorte/Eleanor Friede: New York, 1979.) Hardback £5.95, \$8.95; paperback available from Sphere (London) in September, 1980.

*Time Warps*, the most recent addition to Dr Gribbin's list of popular science books, is about time and time-travel. It is broad in its scope; it begins with a discussion of time-telling through the ages, ends with an excursion into Taoist philosophy and the *I Ching*, and touches on Special Relativity, black holes, precognitive dreams and reincarnation in between.

For the most part, the author does not claim to offer any new insights; rather, as he says, to present old ones in a logically ordered structure. These ideas have been collected either from other popular science books, or from science fiction literature, and the book is liberally sprinkled with direct quotations from these sources. The author's own contribution consists of an explanation of déjà-vu experiences, all forms of dreams, and reincarnation in terms of travel "sideways in time". He postulates the simultaneous existence of all possible universes, and his theory is that dreams and similar phenomena arise from psychic contact with occurrences in some other universe, perhaps one very similar to our own. The beauty of this is that it explains not only dreams which come true, but also those which don't. Dr Gribbin may or may not be the first person to have thought of this idea, but as far as I know, he is the first to admit to it.

This book is aimed at a wide non-scientific audience. It is therefore particularly reprehensible that some of the most important scientific statements are wrong. For example, most of section II is based explicitly on the following incorrect argument. The steps are: (1) Einstein's Theory of General Relativity predicts that under some circumstances massive objects such as stars will collapse to form rotating black holes; (2) these black holes are described by the Kerr metric; and (3) one can therefore travel through a rotating black hole into a new universe. Statements (2) and (3) are false. The misunderstanding arises because the Kerr solution contains paths connecting the interior of a black hole with other regions of the solution, which could be

construed as new universes. Unfortunately, this solution is both vacuum (that is, it contains no matter) and stationary, so it does not represent a realistic collapse. Nor can it have a real observer moving in it (let alone a spaceship). Furthermore, perturbation analysis shows that solutions which resemble Kerr outside the horizon, but which could represent a realistic collapse and contain observers, cannot be extended through the inner horizon into a new universe. The point is that even infinitesimal deviations from the special symmetries of the Kerr solution (such as would be caused by the existence of a particle of matter) drastically alter the structure of the interior solution and destroy the supposed gateway to the new universe (see McNamara, *Proc. R. Soc.* **358**, 499; 1978). It is therefore generally believed that a rotating black hole singularity is not as Gribbin puts it "a different kettle of fish" from a non-rotating one—it is the same kettle. Travellers falling through the horizon could never escape and would eventually be crushed. Appropriately, the incorrect claims made in the book are accompanied by the wrong diagram: the Penrose diagram of a non-rotating charged black hole is shown.

The remaining passages about physics are, on the whole, accurate. These include good introductions to elementary quantum effects, and to the time dilation effects of Special and General Relativity, although even these are marred by a grotesque analogy between velocities and angles on a circle ( $v < c; \theta < 360$ ), and also by the statement that time for an astronaut in closed orbit goes slower than time on Earth: it goes faster if the orbital radius is greater than one-and-a-half times the Earth's radius.

The passages not concerned with physics are characterised by their superficial and tendentious style. The description of Stonehenge as an astronomical computer, which opens section I, is typical. It is gleaned largely from the books by Hawkins (*Stonehenge Decoded*; Souvenir: London, 1967) and by Hoyle (*From Stonehenge to Modern Cosmology*; Freeman: San Francisco, 1972). No mention is made of the review by Professor R. J. C. Atkinson, entitled *Moonshine on Stonehenge* in which much of Hawkins' book is shown to be scientifically and archeologically unsound (*Antiquity*, 1966) or of the correspondence in the 1967 volume of *Antiquity*, where comments range from "dubious" to "untenable". The section then progresses to the subject of clocks, which is illustrated by a picture of a sundial, apparently capable of "all the accuracy

of a modern clock". It concludes with a discussion of time paradoxes and the meaning of time. The level of debate here, as typified by the subsection headed "Temporal Pigeon Holes and the Cosmic Postman", is most politely described as lightweight.

Clichés, polysyllabic humour, and other forms of turgid jocularity abound in this section. If you get past "Meanwhile, the poor man in the street was harried along, willy-nilly, into the 20th century", you are confronted with "intrepid circumterrestrial travellers", their "staid counterparts back home", the "change of date situation" and the fact that "even the common man and woman must come to grips with the subtleties of horological hairsplitting".

More serious, however, is the pernicious tendency to populate the book with 'goodies' (in whose work the author sees support for his theories) and 'baddies'. Thus the goodies are "respectable physicists, schooled in the best scientific tradition", "very solid members of the community", and "very sober scientists with impeccable academic credentials and years of research experience". On the other hand, we read that "Many theorists have an innate dislike for white holes, perhaps because they are only just coming to terms with the implications of black holes, and don't want to move too fast too soon"; that "archeologists cannot bring themselves to accept the subtleties which astronomers find in the Stonehenge computer"; that "there is not enough evidence yet to persuade the doubters" (for the existence of tachyons); and, incredibly, that Dr Gribbin sometimes wonders whether the "verbiage" in philosophical articles is not just "window dressing, to frighten off . . . people who are not 'philosophers'". Interested readers will find plenty more similar examples throughout the book.

Much the same can be said of section III, which purports to relate Eastern Philosophy to Western Science. To be fair, I think that this section will appeal to people with a taste for bizarre interpretations, and many readers will want to follow up the ideas in the bibliography provided. I cannot take these interpretations seriously, because they fail to explain the basic mechanisms and so seem to have no advantage over many less outlandish theories.

A glance at this review will reveal that *Timewarps* is likely to become a best-seller, and that many people will learn a lot of new ideas from it. It is a pity that it was not written with greater regard for accuracy. □

Stephen Siklos is a Research Assistant in Applied Mathematics at Queen Mary College, University of London, UK.

# Sophisticated astronomy

Euan W. MacKie

*Megaliths and Masterminds.* By P. Lancaster Brown. Pp. 246. (Robert Hale: London; Scribners: New York 1979.) £5.50; \$14.95.

THE title suggests that here is another attempt to capitalise on the increasing interest, at many levels, in the evidence for sophisticated astronomical practices in the monuments of Neolithic and Early Bronze Age Europe. There must be at least a dozen books on the market at present with similar titles, and each with a picture of Stonehenge or some other megalithic site on the jacket, so the reviewer may be forgiven for having become somewhat hard to please in this area. These books vary considerably in quality, from the frankly mystical, through orthodox archaeological textbooks to excellent explanations of a difficult and complex subject (see *Nature*, 275, 75; 1978). One may well ask, what is the purpose of another one unless it includes original research or new ideas?

Mr Lancaster Brown in fact ranges more widely than the megaliths of the title, which he correctly defines as including both the standing stone sites of Britain and Brittany and the chambered burial mounds of Atlantic Europe from Spain to Scandinavia (although the latter also include dry-walled constructions and, if the collective burial rite is thought to be the decisive linking feature, some rock-cut tombs as well, which are in no sense megalithic). He has chapters on almost everything connected with astronomy in the ancient world, starting with Alexander Marshack's 'lunar notation' scratches on Palaeolithic bone implements. However, his suggestion that these marks, dating to well before 12,000 years ago, may be ancestral to the Irish Ogham script of less than 2,000 years ago will scarcely find favour with philologists and simply shows that speculating in the historical disciplines can seem too easy to the layman.

The author is, however, very interesting on the early development of research into archaeoastronomy and

ancient metrology, and this is perhaps the most useful part of the book. We are given vivid accounts of Sir Norman Lockyer, L. Piazzi Smyth and Sir Flinders Petrie at work among the temples, pyramids and obelisks of ancient Egypt and of the evolution of thought about astronomical qualities in British prehistoric sites from the seventeenth century onwards. It is very useful to be reminded that many of the modern ideas about ancient astronomy and metrology, developed in such detail by the Thomms, in fact derive from those of earlier workers, and salutary to learn again that some of these became obsessed with their theories to such an extent that they ignored or derided the historical and archaeological evidence. It is true that archaeologists were often of little help, usually being innately sceptical about archaeoastronomical ideas, but they were sometimes faced with such amazing nonsense that their scepticism is understandable.

The author provides one classic example from Lockyer's 1909 book on Stonehenge in which he discussed the living quarters of the astronomer-priests who, he assumed, were at work in Neolithic Britain. He supposed that damp was a severe problem so that shelters were needed, but assumed quite arbitrarily that the people of 4,000 years ago were entirely ignorant of carpentry. Thus they had to live in the megalithic chambered tombs of the period which were supposed to have been equipped with stone doors. (One would scarcely be surprised to read further that the doors often jammed, thus explaining the skeletons frequently found inside!) Even 70 years ago British archaeology had advanced far beyond that; presumably Lockyer had never entered a museum and seen a stone axe. Memories of this kind of thing still help to perpetuate a divide between workers like the Thomms and many orthodox archaeologists.

These historical insights are very useful but the chapters on the astronomy of the ancient Babylonians and of the American Indian civilisations are too brief to be of more than casual interest. Presumably the section on ley lines and 'geomancy' was included as another warning about the eccentric ideas that still flourish on the fringes of megalithic astronomy and which also help to keep many archaeologists at a distance. Perhaps this very breadth of coverage conceals another danger. The author often gives guidance and opinions on the present state of our knowledge of Neolithic Western Europe but these are based primarily on the technical archaeoastronomical evidence, itself only a small fragment of the total knowledge we have of the period concerned.

For example, there is not one but two vitally important aspects of hypotheses about the 'masterminds' among the megalith builders. The first of course concerns the plausibility of the sites claimed as observatories, or as showing high meteorological skill in measuring, and has been discussed extensively many times: this book deals mainly with it. However, the question of what kind of social organisation the people concerned had is an equally important but much trickier subject; it is rarely touched on by archaeoastronomers and their followers as it depends mainly on more orthodox archaeological evidence as well as on anthropological knowledge. There is no problem in ancient Egypt and Babylonia, or in Mesoamerica, which were urban societies known to have had specialist classes of priests and wise men, but what about Neolithic Europe? The population there was in a pre-urban stage and the usual view is that it was much more simply organised, not stratified into classes, and that it certainly did not possess élite orders of astronomer-priests and wise men of the kind which should have existed even if only half of what Professor Thom claims is correct.

The problem is whether the most important Neolithic sites and artefacts can be reinterpreted in terms of such a stratified, theocratic society. If none can, then the case for sophisticated ancient astronomy becomes much harder to maintain, no matter how impressive the technical evidence. The reviewer recently devoted half of an entire book (*Science and Society in Prehistoric Britain*, 1977) to raising this problem, and to making a start on resolving it, but feels he still has some way to go before convincing all his colleagues. Mr Lancaster Brown, however, only brings up the problem in a few lines in the final chapter, saying simply that we can be sure that such an élite class existed and that "Archaeological field evidence strongly supports this idea". Neither the book cited, nor Aubrey Burl's fundamental work *The Stone Circles of the British Isles* (1976) is mentioned anywhere and one must regretfully conclude that this is a further example of the idea that it is enough to be familiar mainly with the specialised archaeoastronomical evidence. Yet that is only the start of the journey, providing a new and clear window on to the past in addition to many older ones, by means of which our very complex but fragmentary picture of life in Neolithic Britain and Europe may eventually be substantially modified. □

Euan W. MacKie is Assistant Keeper in Archaeology and Anthropology at the Hunterian Museum, University of Glasgow, UK.

● In the review of *Physical Chemistry: Principles and Applications for the Biological Sciences* by Tinoco, Sauer and Wang, (*Nature*, 278, 85; 1979), it was incorrectly stated that a paperback edition had been published. A hardback edition only is available from Prentice-Hall International at £12.95, with a paperback *Solutions Manual* at £2.55.

## THE LANGUAGE OF SCIENCE

### Rate Processes of Extractive Metallurgy

edited by **Hong Yong Sohn**  
and **Milton E. Wadsworth**

This book explores significant areas of extractive metallurgy from the perspective of heterogeneous kinetics. Special emphasis is given to rate processes, fundamental mechanisms of reaction, and data for engineering applications. approx. 465 pp., illus., 1979, \$42.50 (\$51.00/£26.78 outside US)

### Surface and Colloid Science Volume 11

#### Experimental Methods

edited by **Robert J. Good**  
and **Robert R. Stromberg**

The contributors to this volume offer authoritative, critical essays on a number of experimental techniques in surface and colloid science. They evaluate several methods of study, including electron probe microanalysis, measurement of contact angles, pendant drop methods of measuring surface tension, microelectrophoresis, and detergency. 360 pp., illus., 1979, \$35.00 (\$42.00/£22.05 outside US)

### Pulverized-Coal Combustion and Gasification

#### Theory and Application for Continuous Flow Processes

edited by **L. Douglas Smoot**  
and **David T. Pratt**

This volume provides a comprehensive and much-needed treatment of analytical modeling of coal reaction processes, emphasizing those processes utilizing finely pulverized coal entrained in a gaseous phase. Topics discussed include turbulent and laminated reacting multiphase systems, gas-particle conductive interactions, gas-phase combustion, pollutants, computer predictions for coal gasifiers, and recent trends in research and development. 352 pp., illus., 1979, \$39.50 (\$47.40/£24.89 outside US)

### Applied Chemical Process Design

by **Frank Aerstlin** and **Gary Street**  
with a foreword by  
**K. D. Timmerhaus**

This handy, concise reference manual, written for use in the office or in the field, provides chemical process engineers with a compilation of many useful procedures for the evaluation of preliminary design of new chemical process equipment. 312 pp., illus., 1978, \$25.00 (\$30.00/£15.75 outside US)

### Topics in Surface Chemistry

edited by **Eric Kay**  
and **Paul S. Bagus**

This volume examines surface studies in electrochemical systems, ordered arrays of organic molecules at surfaces and interfaces, atomic and molecular scattering from surfaces, aspects of surface chemical bonding, and optical excitations at surfaces. A volume in *The IBM Research Symposia Series*. 416 pp., 1978, \$42.50 (\$51.00/£26.78 outside US)

### Chemical Kinetics and Transport

by **Peter C. Jordan**

This new text, designed for use in advanced undergraduate and graduate level courses, examines equilibrium kinetic theory, transport in both gas and solution, phenomenology, mechanisms of thermal and photochemical reaction, single-collision chemistry and calculation of thermal rate constants. Numerous examples are included to illustrate general principles. 384 pp., 1979, \$21.50 (\$25.80/£13.55 outside US)

Available from **John Wiley & Sons Limited** in the United Kingdom, Europe, and the Middle East, excluding Israel.

### Photoelectrochemistry

by **Yu. Ya. Gurevich**  
**Yu. V. Pleskov**  
and **Z. A. Rotenberg**  
translated from Russian by  
**H. Wroblowa**  
translation edited by **H. Wroblowa**  
and **B. E. Conway**

Based on an original Russian language work, updated and revised in conjunction with recent developments, *Photoelectrochemistry* presents the theory of photoemission in a novel and accessible fashion that does not require familiarity with quantum mechanics. Special emphasis is also given to the close ties among photoemission, electrochemical, and radiation-chemical problems. In addition, theoretical formulas are presented at the beginning of experimental sections, enabling the reader to use the formulas as a guide while exploring the test procedures and results. approx. 260 pp., illus., 1979, \$39.50 (\$47.40/£24.89 outside US)

### Quantum Electrochemistry

by **John O'M. Bockris**  
and **Shahed U. M. Khan**

This work emphasizes the molecular model approach in electrode kinetics, while also recognizing the contributions made from the continuum dielectric viewpoint. This important, breakthrough volume will serve as both a text for graduate students and an interdisciplinary guide for the practicing electrochemist. approx. 510 pp., 1979, \$49.50 (\$59.40/£31.19 outside US)

### Aspects of Mechanism and Organometallic Chemistry

edited by **James H. Brewster**

Dividing this subject matter into two broad groups—the interplay of structure and mechanism, and the use of organometallics in synthesis—this volume provides an extensive, broadly based examination of the most recent developments in mechanism and organometallic chemistry. 362 pp., 1979, \$39.50 (\$47.40/£24.89 outside US)

### Correlation Analysis in Chemistry Recent Advances

edited by **N. B. Chapman**  
and **J. Shorter**

Drawing upon research from a wide range of chemical and related sciences, internationally renowned scientists examine in detail the various applications of correlation analysis. The traditional areas associated with Hammett and Taft, as well as the numerous applications of correlation analysis to spectroscopy, are reviewed, and an extensive critical compilation of substituent constants is offered. 560 pp., illus., 1978, \$49.50 (\$59.40/£31.19 outside US)

### Fundamental Research in Homogeneous Catalysis Volume 2

edited by **Yoshio Ishii**  
and **Minoru Tsutsui**

*Fundamental Research in Homogeneous Catalysis* disseminates the latest information for increasing selectivity of desired end products and decreasing waste of chemicals and energy resources in numerous industrial processes. This volume examines such topics as molecular metal cluster compounds, supported metal complex catalysts, and asymmetric catalysis. 316 pp., 1978, \$32.50 (\$39.00/£20.48 outside US)

### PLENUM PUBLISHING CORPORATION

# Comparative Planetology

edited by C. Ponnamperuma

January 1979, 288pp., £10.40/\$16.00 0.12.561340.7

Proceedings of the Third College Park Colloquium on Chemical Evolution and Comparative Planetology held on Sept. 29—Oct. 1, 1976 at the University of Maryland.

This volume presents, in comparative fashion, the latest findings of numerous planetary missions. Prominent astronomers, geologists, chemists, and biologists discuss topics vital to solving the mysteries of the origin and evolution of life in the solar system, including the interiors of planets, crustal evolution, the origin of planetary atmospheres, and questions of life itself. This volume will be of great interest to the growing body of scientists interested in the problems of the origin and evolution of life in the solar system.

Volume 12 in the Benchmark Papers in Behaviour Series

## Critical Periods

edited by J. P. Scott

1978, 400pp., £19.15/\$29.50 0.12.787453.4

**Section Headings:** Critical Periods in Embryonic Development: Discovery of the Phenomenon and Early Statements of the Concept. Critical Periods in Behavioral Development. Critical Periods in the Development of Social Attachment. Critical Periods for Learning. Critical Periods in Physiological Organization. The Theory of Critical Periods.

Published by Dowden, Hutchinson, and Ross, Inc. Distributed World-Wide by Academic Press, Inc.

## The Biology of the Monotremes

M. Griffiths

February 1979, 376pp., £20.15/\$31.00 0.12.303850.2

**Contents:** The Discovery and the General Anatomy of the Monotremes. The Different Kinds of Monotremes, Distribution, Movements, the Crural System and Genetics. Food and Feeding Habits. Digestive Organs and Digestion. Miscellaneous Physiology. Temperature Regulation. Endocrine Glands and the Glands of the Immune System. Special Senses, Organization of the Neocortex, and Behavior. Reproduction and Embryology. Lactation, Composition of the Milk, Suckling, and Growth of the Young. The Affinities of the Monotremes.

## Immunological Methods

edited by I. Lefkovits and B. Pernis

1979, 467pp., £23.40/\$36.00 0.12.442750.2

**Contents:** S. Fazekas de St. Groth, The Quality of Antibodies and Cellular Receptors. J.-C. Jaton *et al.*, The Isolation and Characterization of Immunoglobulins, Antibodies and Their Constituent Polypeptide Chains. B. A. Moss, Peptide Mapping at the Nanomole Level. B. ## Marine Natural Products

Chemical and Biological Perspectives Volume 2

edited by P. J. Scheuer

February 1979, 408pp., £24.70/\$38.00 0.12.624002.7

**Contents:** S. Liaaen-Jensen, Marine Carotenoids. L. J. Goad, The Sterols of Marine Invertebrates: Composition, Biosynthesis, and Metabolites. W. Fenical, Diterpenoids. B. Tursch *et al.*, Terpenoids from Coelenterates. J. J. Sims *et al.*, Applications of  $^{13}\text{C}$  nmr to Marine Natural Products.

**Plant Disease: An Advanced Treatise**

## **Volume 3: How Plants Suffer from Disease**

**edited by J. G. Horsfall and E. B. Cowling**

**February 1979, 488pp., £26.65/\$39.50 0.12.356403.4**

Volume 3 is devoted to the dysfunctions that occur in plants when they are ill. It examines the many types of pathogens that interfere with the systems that comprise photosynthesis, respiration, transpiration, food transport and storage, mineral nutrition, regulation of growth, symbiosis, reproduction, mechanical support, permeability, transcription, translation, and intermediary metabolism. The contributors synthesize the latest findings, indicate promising directions for further research, and emphasize practical applications of our knowledge of plant pathology.

**A Volume in the P&S Biomedical Sciences Symposia Series**

## **Neuronal Information Transfer**

**edited by A. Karlin, V. M. Tennyson and H. J. Vogel**

**January 1979, 496pp., £27.60/\$42.00 0.12.398450.5**

**Sections:** Opening Address: Biogenic Amine Systems. Cholinergic System. Amino Acid Systems. Brain Peptides and Opiate System. Cyclic Nucleotides. Neuronal Structure and Development.

**A Volume in the P&S Biomedical Sciences Symposia Series**

## **Nucleic Acid-Protein Recognition**

**edited by H. Vogel**

**1977, 616pp., £28.05/\$39.50 0.12.722560.9**

This volume concentrates on a cross section of defined biologically significant nucleic acid-protein interactions, at least some of which appear to be governed by code-like rules.

The topics cover: the machinery of DNA synthesis, including "melting" proteins; DNA packaging, with emphasis on DNA-histone interrelations; eukaryotic, prokaryotic, and viral DNA-dependent RNA synthesis; the recognition of double-helical nucleic acids by proteins in general and by repressors in particular; restriction endonucleases and DNA site recognition; tRNA's in relation to their structure, their biosynthesis, reverse transcriptase, recognition by synthetases, and ribosomal interactions; the synthesis of ribosomes and interactions in the initiation and elongation processes of protein synthesis; recognition features in RNA-dependent RNA synthesis; RNA processing; and ribonuclease-nucleotide recognition. To biochemists, biophysicists, and molecular biologists, as well as cell biologists, microbiologists, geneticists, and other biomedical scientists, this volume addresses itself as a guide to research, an aid in teaching and graduate study, and an extensively documented source of reference.

**A Volume in the Materials Science and Technology Series**

## **Solid Electrolytes: General Principles, Characterization, Materials, Applications**

**edited by P. Hagenmuller and W. van Gool**

**1978, 576pp., £33.80/\$52.00 0.12.313360.2**

Fast ion transport in solids is of increasing interest to solid state chemists and physicists, electrochemists, and device engineers. This broad, up-to-date survey of theory and applications of solid electrolytes reflects the growth of a field (also known as superionic conductors) that has expanded tremendously during the past ten years. Part One covers the theories which are currently being developed, as well as the utilization of many physical methods. Part Two classifies the materials according to their physical-chemical characteristics. Current and potential applications of solid electrolytes are dealt with in Part Three. The book stresses the interdisciplinary nature of the subject and contains contributions from specialists of many countries, including physicists, chemists, electrochemists, solid state scientists, and device engineers. Providing a coherent view of a rapidly developing field, the volume will be valuable to a wide range of interested scientists.

## Addison-Wesley Advanced Book Program

Classic Texts . . .

### MOLECULAR ORBITAL THEORY

An Introductory Lecture Note and  
Reprint Volume

C. J. Ballhausen and H. B. Gray

"A very concise exposition of the applications of molecular orbital calculations to inorganic chemistry . . . Suitable for grad students and advanced undergrads interested in the theory of structure" *Choice*

1964 (5th printing, 1978), xii, 274 pp.  
Pbk. 0-805-30451 \$9.50

### COMPLEX CARBOHYDRATES

Their Chemistry, Biosynthesis,  
and Functions

A Set of Lecture Notes

Nathan Sharon, *The Weizmann Institute of Science*

" . . . a detailed, up-to-date review on the chemistry, biosynthesis, and functions of glycopeptides and glycoproteins . . . Professor Sharon's style of writing is easy to follow; his explanation is lucid; and his enthusiasm for the subject adds to the quality of the text."

*Journal of Chemical Education*

1975 (2nd printing, 1978), xx, 466 pp., illus.  
Pbk. 0-201-07323-4 \$14.50

### SECOND EDITION, revised and enlarged ELEMENTS OF QUANTUM THEORY

Frank J. Bockhoff, *Cleveland State University*

" . . . exposition is simple, entirely clear, and accurate; such a presentation is worthy of a student's study time. The derivations are easy to follow, use standard notation, and are comfortably supported by appropriate words of guidance and simple diagrams . . . This is a good book from which to learn quantum theory. Care for the beginning student is apparent throughout."

*Journal of the American Chemical Society*

1976 (2nd printing with corrections, 1978) xii, 332 pp., illus.  
Hdbnd. 0-201-00799-1 \$21.50

### INTRODUCTION to STEREOCHEMISTRY

Kurt Mislow, *Princeton University*

This short text provides a sufficient background for the student to solve independently most of the complex problems in this area of organic chemistry. Each section is followed by about 20 questions and problems which are designed not only to test understanding but to advance the student beyond the descriptive material. Answers to exercises are provided.

1965 (7th printing, 1978), xii, 194 pp., illus.  
Pbk. 0-805-37101-X \$11.50

## Bacterial Cell Pastes

**Escherichia coli** MRE 600

The original ribonuclease free strain, buffer washed.  
(Minimum quantity 2kg @ £210)

**Bacillus stearothermophilus** NCA 1503

Grown at 60°C the source of many thermostable enzymes.  
(Minimum quantity 1kg @ £245)

**Escherichia coli** RY 13

Contains restriction endonuclease Eco RI and Eco RI<sup>+</sup>.  
(Minimum quantity 2kg @ £210)

**Thermus aquaticus** YT-1

Grown at 70°C, the source of thermostable enzymes including restriction endonuclease Taq YI.  
(Minimum quantity 0.5kg @ £310)

**Escherichia coli** B

A source of ribosomes, DNA polymerase I, RNA polymerase, DNA ligase and exonuclease III.  
(Minimum quantity 2kg @ £190)

**Micrococcus lysodeikticus** NCTC 2665

A source of catalase.  
(Minimum quantity 2kg @ £210)

All these products can be supplied to overseas customers. 48 other types of cell paste are also available.

The listed products are offered at the quoted sterling prices, which remain firm until 31 March 1980, subject to availability. Prices include packing in dry ice, and delivery on UK orders, which are subject to VAT at ruling rates. Overseas orders are subject to transport charges at cost. For listed items please send your official order to the:

Porton, Salisbury, SP4 0JG, Wiltshire, UK.

## Biological regulation processes

*Biological Regulation and Development*. Vol. 1: Gene Expression. Edited by R. F. Goldberger. Pp. 558. (Plenum: New York and London, 1979.) £24.88.

THE motivation to produce this inaugural volume of a multi-author treatise on regulation is that it would be productive to approach the subject in a way that cuts across traditional boundaries. The editors aim to avoid bringing together all possible facts relevant to a particular operon, virus or biosynthetic system. For instance, no one person works on suppression *per se*, only on aspects of the phenomenon. The actual chapter by Steege and Söll on suppression successfully picks up the various threads from many different laboratories. This approach, however, means that the same system is often discussed from different points of view by different authors. In a few places this needs some stronger editorial control and cross reference to assist readers with less experience in these areas. Dia-

grams of the same system sometimes appear quite differently in consecutive chapters. The chapter on regulation of DNA replication by Lark suffers from a complete lack of diagrams. In other chapters there is some obvious duplication of material which can be irritating. On balance, however, these problems do not greatly detract from what turns out to be a stimulating set of contributions stressing the essential concepts that underline our knowledge of regulation of gene expression. The book will be of considerable value to senior undergraduates, to postgraduates and to their teachers. Individual chapters deal mainly with regulation in microorganisms but recurrent themes are evolution of regulatory mechanisms and to some extent the relationships between prokaryotes and higher organisms. Later volumes must expand on this latter aspect but perversely no indication is provided, at least in this volume, of future contents.

The initial chapter by Goldberger covers general strategies of genetic regulation and provides a frame of reference for the discussions of operon complexity by Campbell and autogenous regulation by Savageau. Clarke develops the evolution theme with the

view that regulatory systems can be potent agents of evolutionary change. The chapters that follow deal with the relevance of DNA sequence and conformation. Pribnow's chapter on control signals should really be followed by the two more physicochemical contributions from Von Hippel and Sobell on the specificity of DNA-protein interactions and implications of DNA conformation. These latter chapters, careful consideration. Steitz then though speculative in places, deserve stresses the importance of RNA-RNA interactions, especially in ribosome function and proposes that mRNA effectively selects protein molecules that facilitate such interactions. Cortese follows with a review of the various functions of tRNA that are secondary to, or derived from, its primary function as amino acid adaptor. Finally, Maaløe amply demonstrates the stimulating but complex challenge of evaluating the possible interplay of all these various regulatory mechanisms in the growing organism (mainly *E. coli*).

Roy H. Burdon

Roy H. Burdon is Professor (Titular) of Biochemistry at the University of Glasgow, UK.

## Thermal neutron scattering

*Introduction to the Theory of Thermal Neutron Scattering*. By G. L. Squires. Pp. 260. (Cambridge University Press: Cambridge, London, New York and Melbourne, 1978.) £16.

THERMAL neutrons are used widely to study structures and correlations in solids and liquids. They have just the right wavelength for atomic physics; and, as nuclear scattering takes place effectively at a point, one can use the scattered intensity to disentangle the motion of atoms. The momentum transfer dependence of the scattering is the Fourier transform of the spatial structure, and the energy dependence is likewise the Fourier transform of the time dependence of correlations. The magnetic moment of the neutron is a valuable bonus, sensitive to the magnetic structure of materials at the atomic level.

There are several textbooks on the physics which emerges, and on the techniques, but most authors content themselves with rough and ready derivations (or simply quoting) the rather complicated expression for scattering cross sections which are needed for quantitative analysis. This can be hard on research students wanting to extrapolate formulae to fresh situations and

wanting to grasp from first principles the meaning of phonons, magnons, spin waves and correlation functions. Gordon Squires' book fills this gap admirably. As the title implies, the book is aimed at deriving the formulae systematically and rigorously. It is the Goldberger and Watson of thermal neutron physics. Students will appreciate the beautifully precise, lucid and explicit algebra, which follows smoothly from undergraduate quantum mechanics. The material is extraordinarily well organised; there is great care over nomenclature, no mistakes and no missing lines. On the other hand, the casual reader might find the subject a bore, and even the dedicated reader will have to reflect carefully on the objectives of the formulae and the physical implications of each factor or approximation. To help his understanding, there are several problems, many of them quite hard, with solutions. Formulae are illustrated briefly with experimental results, but there is no systematic attempt to explore the physics which emerges from thermal neutron scattering.

This volume will be a valuable prop to the experimenter wanting to be sure of the foundation of his subject.

## Microbial life in extreme environments

*Thermophilic Microorganisms and Life at High Temperatures.* By T. D. Brock. Pp. 465. (Springer: New York, Heidelberg and Berlin, 1978.) \$29.70; DM54.

THIS book collates the ecological studies Professor Brock initiated and directed on microbial life in the hot springs of Yellowstone, some 1,200 miles from his University campus and at an altitude where water boils at 92 °C. The scope of the project was admittedly limited initially, but in the light of discoveries of unknown microbial species adapted to live in a variety of extreme environments, research ramified to include man-made thermal habitats and hot springs on a worldwide scale.

The objective was to study the structure, biochemical and growth characteristics, evolution and dispersal of such bacteria, blue-green algae and eukaryotic algae which seem to set the limits for life with respect to pH and temperature. Such natural model systems, with the relative constancy of their features, would then make possible deductions about long term ecological consequences of man-produced thermal and chemical pollution of the environment.

The cover picture showing the run-off channel of a Yellowstone hot spring is more suggestive of the scope of the book than its title. *Exploring Microbial Life in Hot Springs* might be a more appropriate title, which better expresses the 'adventure' character of the book.

The book stamps a record of personal achievement by drawing a demarcation line from earlier or contemporary work; it aims at helping future researchers, especially in Yellowstone, with the detailed description of the sites studied (chemical, physical and topographical). Furthermore, it includes valuable unpublished observations, suggests areas for future research and provides a wealth of ideas for *in situ* research approaches and improvised techniques that proved useful where conventional methods could not work or were unavailable. The author's confessions of being often misdirected or "fooled", for example, by *Thermoplasma*, when in fact a new bacterium, *Sulfolobus*, had been isolated, illustrates the complexity and very often deceptive nature of working in an area where no precedent existed.

The seminar style of the book gives the reader both pleasure and a good share of the fascination and excitement

of the field work. The personalised manner in which the book was written is highlighted by the author's comments on his original paper on the genus *Sulfolobus*, that was rejected twice by the *Journal of Bacteriology*; and by the final chapter "Some Personal History" that includes a family and research team photograph.

The book illustrates effectively how research orientation can become usefully multi-directional in the way discoveries developed in a multi-disciplinary fashion, thereby becoming of interest to ecologists, environmental scientists, biochemists and geologists

alike. The author did not even miss the opportunity to comment on his observations on the effects of pH limits on the existence of higher organisms, including insects, frogs, birds, fish and plants.

Finally, this book, if read from cover to cover rather than used as a reference source, has all the elements that make it useful to ecologists. It would also make inspiring introductory reading for new researchers in microbial ecology.

**G. D. Anagnostopoulos**

*G. D. Anagnostopoulos is Lecturer in Microbiology at Queen Elizabeth College, University of London, UK.*

## Liquid structure in relation to their crystalline solids

*The Molten State of Matter: Melting and Crystal Structure.* By A. R. Ubbelohde. Pp. 454. (Wiley: Chichester, UK, and New York, 1979.) £23.50.

THIS book may mark the end of an era: or it may not. Scientific eras overlap, and a severe decimation of the time scale may be needed before the transition between them is marked with any definiteness. Knowledge of the figure of the Earth did not much assist the search for the sources of the Nile, and the Nile is still imperceptible on the geoid. This book is about liquids, and Ubbelohde has chosen its title to emphasise the fact that he will consider their structure in relation to that of their crystalline solids. Thus, attention is focused on phase change, and the relationship between the phases between which the change occurs: but one will find no mention here of the renormalisation group, or the names of Peierls, Landau, Wilson or Kadanoff, nor even, rather surprisingly, of Bernal and Fowler: which is not to say that there is not a wealth of references here to work in the present decade as well as past decades. Conversely, one may read a book about the renormalisation group and find mention of only three or four particular substances, if that. Ubbelohde deals with particular substances, and many comparative tables of the melting parameters of particular classes of substance are a feature of the book. These are instructive, and would be more so if one knew how much confidence to place in them. They seldom contain estimates of error, and sometimes fail to indicate source: there are discrepancies, sometimes minor and sometimes substantial, between values for

the same physical quantity in different tables: for example, the entropy of fusion of NaCl is 6.7 e.u. in Table 8.1 and 6.23 e.u. in Table 8.34. There are quite alarming discrepancies between heat capacity data for solid and liquid alkali metals in Table 9.1 and data for sodium in Fig. 9.1. Contradictory information about the magnetic susceptibility of iron phases at high temperature is given in Fig. 9.7 (p263) and the text on p264.

On p103 the reader is told, as though he should believe it, that for a second-order phase change two free energy surfaces must touch and intersect, with never a mention of bifurcation. Naïve readers must be warned against chapter 14, on "Liquid Crystals", shot through with misconceptions which should never have survived the classic paper of G. Friedel (1922).

Pleas for more observational data are a recurring refrain, and often justified: but, although on p90 the author complains about the lack of information regarding domain formation in order-disorder transformation, he never mentions antiphase boundaries, a keyphrase which could have led him to a wealth of material in the metallurgical literature.

It becomes apparent that several distinct and separate cultures grow on the one substrate of phase transitions. Of these, this book provides a useful literature guide to a substantial part of the physicochemical culture. Those readers who will take the trouble to check and amend the data will be in possession of a well-planned survey of empirical melting parameters, and some liquid properties for various classes of material. Considering the price to be charged, this should have been attended to by the publisher's editor.

**F. C. Frank**

*Sir Charles Frank is Emeritus Professor of Physics at the University of Bristol, UK.*

# The Pump

## Check what it can do for you!

Linear, concave or convex gradient formation by three channels

Different flow rates to three columns by three channels

Undisturbed chromatogram due to minimum pulsation by six gear driven rollers

Flow versatility with three different tube sizes

Can save column repacking

Saves time when clearing bubbles from system by overriding pre-set flow rate

Reliable flow rate (0.6–400 ml/hr) due to electronic load and temperature compensation

Saves bench space. Only 11x11 cm

The Pharmacia Peristaltic Pump P-3 is your ideal general-purpose laboratory pump for column chromatography, density gradient formation and many other biochemical techniques where reliable liquid flows are required.

Its versatility gives you convenience and saves your time and money. Let this pump work for you in your lab. Ask for detailed information today.

## Do you determine moisture contents? It's no longer a calculation chore!

With the new Mettler LP15 Infrared Dryer/PC top-loading balance combination, determining moisture contents is easier than ever before. Whether you are working with fats or other substances – you get reliable results in no time at all.

The weight of the sample does not have to be exactly 1 gram or 10 times or 100 times as much. The microprocessor of the balance handles all the conversions from grams to percent. As the moisture content decreases, the corresponding weight loss is displayed on the PC balance. In percent or in grams, whichever suits you best.

That's how easy it is when you are working with a Mettler LP15 Infrared Dryer.

## D. A. Hems

TO BE a successful scientist requires three attributes: intelligence, hard-work and perspicacity. Intelligence and hard work are not enough; perspicacity, insight, flair—call it what you will—make up a somewhat undefinable third requisite. Dr D. A. Hems, Reader in Biochemistry at St George's Hospital Medical School, London, who died tragically on 2 February 1979, possessed all three qualities. He was just 40, at the peak of his scientific career.

Hems received his schooling at the John Lyon school in Harrow, and entered University College, London as Bucknill Open Scholar in Medicine. At the end of his pre-clinical years, he took an intercalated Hons BSc in Physiology; during his clinical training at UCH he received prizes in neurology, and in obstetrics and gynaecology. On qualifying, he decided to pursue a scientific career, and moved to the Institute of Psychiatry to work on biochemical aspects of brain metabolism under Dr (now Prof.) R. Rodnight; three years later he received his PhD. Intelligence and hard work were clearly two of Hems' attributes.

Hems' interest now lay firmly in metabolism. But not in the elucidation of intermediates or in the properties of isolated enzymes. He realised that this aspect of biochemistry was, by 1966, proceeding on fairly predictable lines. What was lacking, was a proper correlation between the physiological behaviour of an organ and the biochemical activity of its cells. In Oxford, Sir Hans Krebs was developing the technique of whole organ perfusion. So it was to Oxford, on an MRC Research Fellowship, that Hems went in 1966: the first sign of that third attribute.

In 1969 Hems was appointed Lecturer in Biochemistry at Imperial College, under Professor Sir Ernst Chain. He now began to develop what proved to be his major scientific interest: the hormonal control of metabolism, using intact organs and cells. It was clear to him, as to others at this time, that the concept of a specific target organ for a specific hormone was too restrictive. He showed, for example, that the antidiuretic hormone vasopressin also has a direct action on the liver; that action is to stimulate glycogen phosphorylase, but not, as Hems discovered, by way of

cyclic AMP. Another of Hems' interests lay in obesity. With characteristic insight he chose to investigate fat synthesis in liver, rather than in adipose tissue: a choice that is beginning to appear well-founded. More signs of that essential third quality; sadly, fulfillment of Hems' potential was not to be realised.

During his time at Imperial College, Hems established close links with the research being carried out by Dr Anne Beloff-Chain (Lady Chain). He also built up an active group of his own; when in 1976 he was offered a Senior Lectureship in the new Biochemistry Department at St George's, the entire group chose to move with him to Tooting. Hems—Doug to all who were close to him—was at once immensely kind and considerate, helpful and inspiring, and it is easy to see why he was able to attract bright and energetic students, as well as more senior research workers. As a teacher, also, Hems was dedicated to his students.

His scientific achievements led to his appointment as an editor, first for *Clinical Science and Molecular Medicine*, and next of the *Biochemical Journal*. He also played an active part in the Regulation in Metabolism Group of the Biochemical Society.

Hems loved music and poetry; he particularly enjoyed witty and pithy comments on life, and was himself gifted with a dry sense of humour. The latter contributed to his demand as a guest speaker: at the time of his death, he had invitations to lecture at Guildford, London, Cairo, Cambridge and Copenhagen. But however much his scientific colleagues will miss him, it is his widow, Phyl Hems, and his two children Jacky and Clare, who face a sad and lonely future without Doug. It is to them that our sympathy is extended.

C. A. Pasternak

## Ralph Emerson

WITH the death on 12 March 1979 of Professor Ralph Emerson, mycology has lost one of its brightest stars. He was born in New York City in 1912. He studied biology at Harvard obtaining his BS in 1933 and his PhD in 1937. He then came to England with a National Research Council fellowship and worked in the botany school at Cambridge for the next two years. In 1940 he joined the faculty of the University of Cali-

fornia at Berkeley becoming a full professor in 1953 and being chairman of the botany department from 1967 to 1971.

He was elected to the National Academy of Sciences in 1970. He served as president of the Botanical Society of America (1967), as president of the Mycological Society of America (1953) and as vice-president of the British Mycological Society (1971). In 1964 he received the Merit Award of the Botanical Society of America. To the First International Mycological Congress at Exeter in 1971 he contributed a brilliant general lecture which ended in a standing ovation.

His greatest scientific contributions were to the biology of water-moulds especially those belonging to the Blastocladales. Hans Kniep (1881–1930), that great student of sexuality in fungi, discovered in the last years of his life a unique sexual cycle in the water-mould *Allomyces*. Ralph Emerson developed the study of sex in species of that genus in beautiful detail. His 'An experimental study of the life-cycles and taxonomy of *Allomyces*' (*Lloydia* 4, 77–144; 1941) has become one of the classic papers of mycology. He was also responsible for a film 'Syngamy and alteration of generations in *Allomyces*', one of the finest mycological films ever produced. Further, Ralph Emerson made important contributions to the physiology of water-moulds. He found that certain species require an environment with a high concentration of carbon dioxide if resting spores are to be formed, whilst in one species oxygen must be absent if any growth is to occur, a most unusual situation in fungi.

He maintained that, although Blastocladales were clearly not organisms of economic importance, their study could make valuable contributions to fundamental problems. He inspired students and colleagues to undertake work that has fully vindicated this view. He launched Dr Cantino on his productive study of *Blastocladia* which has done so much to illuminate the relationship between biochemistry and morphology. He inspired the late Dr Machlis and his colleagues to investigate the hormone concerned with the attraction of male to female gametes in *Allomyces*. This led in 1968 to the

resolution of the structure of sirenin, the first plant sex hormone to be characterised. All over America there are mycologists of distinction who received their early inspiration from Ralph Emerson.

During the war years 1944–46 he served as microbiologist to the Emergency Rubber Project in the United States which led him temporarily into the field of thermophilic organisms, particularly fungi responsible for development of high temperatures in compost heaps. After the war, although Blastocladias remained his main research area, he continued his war-time interest and with Dr Cooney was responsible for an important book *Thermophilic Fungi* published in 1964.

Ralph Emerson was much concerned with the basic causes of the student troubles on the Berkeley campus in the late sixties. In particular he felt it his duty to respond to his students' demands for relevance in mycological teaching. He immediately set to work to organise what he described as 'a running story of fungi and mankind with whatever minimum mycological technicalities had to be provided'. He devised a course that was both academically sound and excitingly relevant.

Ralph Emerson was a man of strong

character and great personal charm. Not only was he a research worker of outstanding ability, but he also wrote and spoke with elegance and clarity. His enthusiasm for his subject and for the experimental approach was unbounded. His former students and mycologists throughout the world mourn the loss of an eminent scientist. Above all he was a very special kind of person.

C. T. Ingold

## David Zimmerman

IT WAS with extreme regret that I heard of the sudden death of Dr David Zimmerman, who died on 10 November 1978 of haemorrhage following an injury to his eye by a tennis ball.

He came to England in the sixties with an MSc in physics from the University of Wisconsin and joined Dr Aitken in the Research Laboratory for Archaeology in the University of Oxford. Here he became one of the most productive research workers in the new field of thermoluminescent dating.

One of the factors which made absolute dating difficult was lack of homogeneity in the samples of ancient pottery to which it could best be applied. Dr Zimmerman developed a way of avoiding this problem by the separating out of grains in the sample which

were small compared with the range of alpha particles and in which therefore a statistical uniformity could be expected.

After gaining a well-deserved D.Phil as a result of this work, he returned to the United States where he continued to work on thermoluminescent dating of pottery at Washington University, St. Louis. Here he explored the possibility of using the zircon inclusions which usually contain so much uranium and thorium as to be almost entirely unaffected by background radiations, which are often impossible to estimate accurately.

Dr Zimmerman had many interests outside physics which he applied with characteristic success; for example he obtained a Blue at Oxford for badminton and played tennis with enthusiasm (Intercollegiate-Caltech); it was tragic that this should have led to his death. He enjoyed walking and camping and was interested in piano music. He was forty years old at the time of his death and has left a wife, Joan who was a contemporary research worker in 'TL' at Oxford. During the last twelve months he had started a valuable newsletter *Ancient TL*. His death is a very great loss to the field of thermoluminescence as well as to his large number of friends.

J. H. Fremlin

# FREE: THE PARK LANE LABORATORY.

Once again this professional exhibition will be open to scientists and other qualified visitors in the luxurious environment of Grosvenor House. And with *free* admission.

At Laboratory '79 you'll find the big corporations and the smaller innovators side by side – and not dwarfed by expansive displays.

The most important names with some of the most renowned scientific equipment will be there:

DuPont; Gallenkamp;  
LKB Instruments;  
MSE; Perkin-Elmer; Vickers  
–and lots more.

Be here: 11-13 September!

**A NEW DECADE – 1980 IS LESS  
THAN 6 MONTHS AWAY.**

Laboratory '79 will provide you with an opportunity to plan for the '80s.

All exhibitors have the same type of modular stands.  
All exhibitors have the same sizes.

Circle No. 12 on Reader Enquiry Card.

So you can see who you want to see without route

marches (and exhibition feet!).

And you'll enjoy it.

**IT'S FREE. ABSOLUTELY FREE.**

If you complete the coupon and attach a stamp by its corner, we'll send you a free admission ticket.

Then, when you arrive at Laboratory '79 we'll also give you a free catalogue crammed full with information (and, we believe, well worth the trip alone).

We're not being generous, of course; we're just absolutely committed to making Laboratory '79 a better place to go. A better, more effective, central London exhibition.

You'll come?

*We're giving a T.I. 51-111 calculator away to one visitor in every thousand – if his registration is neat enough to read!*

Send me my free ticket please, post haste.

Attach a 2nd class stamp by its corner here, please

# ELECTROPHORESIS

## A state of the art report from Marine Colloids

---

### **SeaKem® Agarose is the preferred medium for electrophoresis**

---

Marine Colloids is the world leader in agarose with more experience and more end-use-specific types of agarose than any other manufacturer. Tell us the properties you want and we'll supply the agarose you need. Ask for a copy of our catalog and price list.

---

### **GelBond™ film is making glass plates obsolete**

---

GelBond is Marine Colloids' tradename for the new transparent, flexible, specially-treated polyester film\* to which freshly-prepared agarose, agar and polyacrylamide gels adhere and remain adhered during use. Its advantages are convenience, permanence and firm adhesion of the gels throughout drying, staining, destaining and storage. Try it once and you'll never go back to glass. Only Marine Colloids offers GelBond film. Ask for a copy of our GelBond bulletin and price list and free samples.

\*Custom manufactured for Marine Colloids by the 3M Co.

---

### **IsoGel™ (No EEO) Agarose. A breakthrough in ISOELECTROFOCUSING**

---

The IEF procedure separates and concentrates proteins on the basis of minute differences in their isoelectric points. Until recently, the application of the IEF technique in continuous media was limited to polyacrylamide gels despite their notorious limitations. With the advent of IsoGel, the many familiar advantages of agarose are now commercially available in a gel medium having no electroendosmosis ( $-M_p$ ). In addition and perhaps most important is its capability of direct and immediate extraction and focusing of proteins from biopsy tissue. Ask for a copy of our new instruction manual which describes the Agarose Isoelectrofocusing technique and provides a recommended procedure for protein analysis.

---

### **For Serum Protein Analysis, GelBond™ film with SeaKem® Agarose offers superior resolution plus**

---

World leaders in Clinical Chemistry now recognize the superiority of SeaKem Agarose and GelBond film over cellulose acetate for routine serum EP. They have come to prefer the convenience, reproducibility, greater yield of diagnostic information and sharp, permanent records provided by SeaKem and GelBond. [AGAROSE GEL ELECTROPHORESIS, submitted by J.-O. Jeppsson, C.-B. Laurell and B. Franzén, Department of Clinical Chemistry, Malmö General Hospital, Sweden, is now a proposed selected method of the ASCC (Clinical Chemistry Vol. 25, #4, 1979)]

# ACHEMA '79

ACHEMA 79, the 19th Chemical Engineers' Exhibition-Congress, is to be held in Frankfurt on June 17-23. This AICHEMA news section gives brief notes on some of the products on show. For more details from the manufacturers circle the appropriate numbers on the card bound inside the cover.

## Krupp

At AICHEMA 1979 Krupp Atlas-Elektronik will be presenting the process video system PVS 1050, an improved version of the colour video system PVS 1100 which has been used for some years in the chemical industry. This new system enables a user who already has a process computer to adopt process video technology at relatively low cost. The PVS 1050 does not require a mass storage unit and serves as a terminal for connection to a control computer via standard interfaces. Colour process diagrams, curves, bar charts and texts are displayed on a screen. The diagrams are created interactively with a light pen and keyboard. Chemical pumps require bearing components made of material resistant to chemicals. Mechanical seals made of the new hardmetal grade GTK, a nickel-bonded alloy developed by Krupp Widia, can also be installed in pumps handling corrosive fluids. These are available with diameters of up to 350 mm. They are made of solid hardmetal or fitted with hardmetal rings which are clamped or soldered in position.

Cutting mill knives are used in the plastics industry for on-line size reduction of the constituents of plastics mixes and for cutting up plastics scrap for recycling. These materials have highly abrasive fillers and the knives thus become blunt quickly. Krupp Widia has developed a new highly wear-resistant hardmetal grade and now supplies mechanically clamped cutting elements for these knives. They can be reground several times, ensure economic production, especially with fibre-glass reinforced duro- and thermoplastics, and have service life of up to 40 times that of conventional steel knives.

At AICHEMA 1979 Krupp Widia will be exhibiting hardmetal-tipped granulator plates for granulating polyethylene. This innovation increases the service life 15-fold compared with the hardfaced design previously used.

**Circle No. 69 on Reader Enquiry Card.**

## Henry Wiggin

The Wiggin exhibit highlights Wiggin's ability to meet all the main international specifications in the manufacture of nickel based alloys for the construction of chemical and petrochemical plant. Among the products to be featured will be the well-known Nickel 200/201, Monel alloys 400 and K500, Inconel alloys 600 and 625 and Incoloy alloys 800H and 825. Recent additions to the range are Corronel alloys B2 and C4 and Alloy G. Alloy G (from Huntington Alloys Inc.) is a high-nickel alloy which, in acidic and alkaline environments, is used for its high level of resistance to pitting and stress-corrosion cracking.

**Circle No. 103 on Reader Enquiry Card.**

Senior Platecoil heat exchanger

## Senior Platecoil Ltd

Senior Platecoil Limited of Watford, England exhibit for the first time at AICHEMA 1979 a range of embossed metal plate-type heat exchangers manufactured by their new hydraulic expansion process. Platecoils are used for heating or cooling process liquids by either immersion in process vessels, incorporated into vessel walls as integral sections or clamped externally to vessel walls. Materials of manufacture are normally high grade carbon steel, AISI 316 stainless steel or commercially pure titanium. Other materials of manufacture include, for example, Hastelloy, Incoloy, Monel or other exotic alloys. Heating or cooling media include steam, hot water, hot oil, chilled water or refrigerants. All Platecoils are pressure tested before despatch and operating pressures can be as high as 22 bar g. Platecoils can be shaped, curved, rolled into full cylinders or even provided with cutouts to give the maximum design flexibility demanded by process engineers.

**Circle No. 102 on Reader Enquiry Card.**

## Büchi

The new Büchi rotary evaporators, R-110, RE-120 and EL-130, are characterised by the following features: completely new design, compact construction, improved stability, robust, smooth quick-action jack, optimum sealing system and electric or electronic speed control.

**Circle No. 101 on Reader Enquiry Card.**

Heraeus change-over assembly for gas cylinders

## Heraeus

New from Heraeus is a low-priced assembly for automatic change-over to a reserve gas cylinder. This automatic change-over assembly, type GM, is most useful in those cases where a continuous supply of gas must be maintained with minimum attendance. The assembly is designed for connection to two gas cylinders (or batteries of cylinders), one of which serves as reserve. It changes over automatically to the reserve cylinder as soon as the first cylinder is empty. The fact that the cylinder is empty and should, therefore, be replaced, is indicated by a red lamp. A buzzer can be provided additionally. The signal will stop only after connection of the new cylinder, which will then serve as reserve. Manual change-over is possible at any time. The change-over assembly may be used only in conjunction with compressed or liquefied gases, such as CO<sub>2</sub>, N<sub>2</sub> and O<sub>2</sub>.

**Circle No. 100 on Reader Enquiry Card.**

## George Kent Group

The George Kent Group are showing a comprehensive range of products including significant new items at the AICHEMA exhibition. The Kent displays form a prominent part of

## Volumetrics Pipettors

50  $\mu$ l, 100  $\mu$ l

Accuracy and reproducibility better than  $\pm 1\%$ . Priced as low as \$2.00 ea.

VOLUMETRICS WORK STATION holds 2 Pipettors and 250 tips (shown without dust cover).

## Pasteur + Plus

DISPOSABLE PLASTIC  
TRANSFER PIPETTES

Regular  
Ultra lean-tubed

A safer alternative to the glass pipette. No bulb to leak, safe one time use without risk of contamination.

For volumes up to 3 ml. 21 to 24 drops/ml delivery.

## Tips

We carry a full line of disposable polypropylene tips for our own and many other pipettors.

## Ultipettes

Excellent for Pasteur pipetting. Five adjustable models: to 1 ml, to 2 ml, to 5 ml. (with air bleed for optional use). 2 ml and 5 ml models also available in PTFE for acids and solvents.

## Finnpipettes

OVER 70,000 IN USE WORLD WIDE.

Accurate, reproducible adjustable micropipetting. 5 instruments to cover the range from 1  $\mu$ l to 5,000  $\mu$ l.

## Steady-State Enzyme Kinetics

Stanley  
Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

**M** MACMILLAN  
PRESS

the BBC Brown Boveri stand. Equipment on display comes from six manufacturing companies in the Kent group—computer based process control systems from Kent Automation Systems, Hitchin; electronic process control instrumentation and flow-measuring equipment from Kent Instruments, Luton; process analytical instrumentation from Electronic Instruments, Chertsey; pneumatic process control instrumentation from Kent-Tieghi, Italy; level instrumentation and electronic recorders, indicators and controllers from Foster Cambridge, St Neots; and gas monitoring equipment from George Kent Electronic Products, Cambridge. On show for the first time is a new generation of integrated electronic process control instrumentation, the P4000 system. Process analytical instrumentation includes equipment for measuring pH, conductivity and dissolved oxygen, and a range of selective ion monitors. Oxygen measuring instruments include the Model 9407 automatic dissolved oxygen system which increases the convenience and reliability of oxygen measurements, even in stagnant conditions, by providing *in situ* remote calibration checks and cleaning. The 8000 series of selective ion monitors is designed for continuous on-stream monitoring of specific-ion concentration. Eight different ions can be identified and measured by models in the series. A new colorimetric analyser for silica will be on show. This is the Model 8061 which provides a continuous readout of silica concentration in the range 0–2,000 p.p.b. This unit has important applications in the power generation industry. A filtration system can be incorporated to allow the monitoring of heavily polluted samples.

Circle No. 99 on Reader Enquiry Card.

### Stanton Redcroft

Stanton Redcroft will be exhibiting a new simultaneous thermobalance-differential thermal analyser for measuring weight and thermal changes of materials. This equipment uses micro-processors and allows the physical and chemical phenomena of many different materials to be studied. The established universal digital temperature programmers will be displayed showing their versatility in operation from desktop calculators. Also on show will be a well established range of thermobalances and differential thermal analysers. Of particular note is the quality control application of the TG 750 in fields such as plastics and food. The flammability field is now rapidly growing, and the complete range of oxygen index test equipment operating at room temperature and up to 400 °C will be displayed.

Other products manufactured by Stanton Redcroft include a hot stage microscope attachment, thermomechanical analyser and mineral insulated thermocouples.

Circle No. 98 on Reader Enquiry Card.

Anhydro pilot spin-dryer

#### Anhydro

Equipment on show on the Anhydro stand includes a new laboratory spin flash drying plant suitable for tests with highly viscous materials such as pastes. Also available is a new compact spray dryer for use as a pilot system.

Circle No. 97 on Reader Enquiry Card.

#### Caldyn

In Caldyn gas impregnation and atomising plants the property of gas/liquid mixtures to have a substantially lower sonic velocity than the gas or liquid alone is utilised to atomise liquids and to generate minute gas bubbles. Liquid and gas are mixed together in the Caldyn CSL nozzle and accelerated to the sonic (critical) velocity of the two-phase mixture. The mixture is expanded to the environmental pressure at the nozzle outlet. Atomisation is achieved with very low energy consumption.

Circle No. 96 on Reader Enquiry Card.

#### Langley Alloys

In addition to their general range of special alloy materials, stainless steels, nickel alloys, cupro-nickel and aluminium bronze, and valves in stainless steel and nickel alloys, special features on the Langley Alloys stand include: Ferralium alloy 255—demonstration of its pitting resistance and crevice corrosion resistance. Ferralium alloy 288—new cast alloy with improved resistance to phosphoric and sulphuric acids. A new cast nickel-molybdenum alloy, Niralium alloy 130, is introduced.

Circle No. 95 on Reader Enquiry Card.

#### V. C. Filters

V. C. Filters, in association with L. B. Holliday & Co. of Huddersfield, have developed and are now marketing multiple cell electrolyzers for use in electrochemical processing. These units are suitable for a variety of electrochemical processes including electro-organic synthesis, 'chlor-alkali' processes such as chlorine/caustic soda, sodium hypochlorite, chlorate and bromate manufacture and the re-oxidation of many inorganic redox species used for oxidation of organic compounds. The electrolyzer contains 1m<sup>2</sup> electrodes and can be readily built up to a maximum of 40 cells per unit. The assembly may be of mono-polar or bipolar arrangement and contains optional ion exchange membranes. Other sizes of electrolyzer are also available, including a small laboratory unit which is completely self contained and can be supplied with various interchangeable electrode materials. The unit can be extended to operate in a bipolar mode by the inclusion of more cells. An intermediate or pilot sized plant is also available.

Circle No. 94 on Reader Enquiry Card.

#### Driam

Driacoater filmcoating equipment from Driam is designed for filmcoating pharmaceutical tablets, hard and soft granulates and pellets with organic solvents and aqueous dispersions. A fluidised bed is developed in the drum of the Driacoater by drying air entering over a rotating distributor by way of hollow ribs immersing into the product bed. By elimination of baffles and development of a fluidised bed, an even mixture, a homogeneous coat as well as a gentle handling, also of very sensitive products, can be achieved. At the same time the counter-current air flow guarantees efficient drying.

Circle No. 93 on Reader Enquiry Card.

Hilge Hygia-Bloc pump

#### Hilge

Hilge are showing a wide range of pumps made of chromium nickel steel for applications in chemical and biochemical engineering, water- and industrial techniques, surface-, airconditioning- and cleaning-treatments.

## Alfa's new 1979-80 Catalog

### NOW WITH ORGANICS.

Alfa, the recognized leader in inorganic and organometallic research chemicals and materials, has added organic chemicals to its new, 1979-80 catalog, to better supply all of your needs from one convenient source.

In addition to its new organic line, the Alfa Catalog includes: • Inorganics and Organometallics • Ultrapure Chemicals • Pure Elements • Puratronic® Products • Analytical Standards and • Research & Safety Equipment... at the lowest industry prices with attractive quantity discounts. Compare for yourself.

This is the one valuable chemicals and materials handbook which you can't afford to be without. Send today for your free Alfa Catalog.

# The programmable computerised image analyser that doesn't need a programmer

You can program the new Quantimet System 23 for your image analysis applications with no computer programming knowledge.

Image analysers count, measure and classify features in images from optical and electron microscopes, photographs, negatives, cine film or macro objects. Applications vary widely and virtually each one requires a different type of analysis routine.

Unlike any other image analyser, the new System 23 incorporates a unique operator-interactive image analysis keyboard which enables you to program the System 23 for your image analysis application **without** using FORTRAN, BASIC or any other exotic programming language.

For example, when analysing features such as particles, fibres, etc., depressing the keys **MEASURE FEATURE COUNT DISTRIBUTED BY**

**LENGTH** results in a frequency distribution of feature length which is displayed on the system monitor as illustrated in the histogram below.

Using a similar sequence of keyboard instructions, the operator can enter experimental variables and compose mathematical expressions such as quadratic equations, derivatives and compound descriptions of feature shape and texture.

Now you can easily develop, test and enter new measurement concepts and store immediate results on the Quantimet monitor or printout. After you have written your analysis routine, store it on a high

speed magnetic disc for future use. When repeating the analysis, insert the disc in the computer, enter the routine number and the System 23 runs automatically. **FILL IN THE COUPON BELOW AND MAIL IT NOW - OR CALL US ON THE PHONE.**

Feature Parameters displayed at each feature assist in analysis of specimen.

Intermediate or final Histograms displayed on monitor. Histograms can be logarithmic, differential or integral.

Image Editor Pen (optional) used on problem specimens to ACCEPT, REJECT, CUT, JOIN or FILL.

**Charles Austen Pumps Ltd**

Charles Austen are exhibiting a comprehensive range of gas, air, vacuum and liquid pumps. These purpose-designed pumps are of small physical size, quiet in operation and simple to service. They are of the membrane type and completely oil free. Flow rates are 0.70 litres per min, pressure  $0.4 \text{ kg cm}^{-2}$  and vacuum  $0.740 \text{ mm Hg}$ . The pumps are used for medical and industrial research purposes, process control instrumentation and in laboratory instruments, for example flame photometers, spectrophotometers, gas and air sampling instruments, environmental chambers, vacuum embedding instruments and ageing ovens. Charles Austen diaphragm liquid pumps are self priming and ideally suited to applications where scavenging is necessary. The range of small centrifugal liquid pumps are used for filtration duties, cooling units and X-ray processing machines. The pumps are used in the following instruments manufactured by Charles Austen: the Vacuum Tweezer, which provides an effective and safe means of manipulating micro-miniature or delicate components during examination or assembly and a completely portable atmosphere sampling unit, the FI Mk. 1, incorporating battery mains charger, flowmeter with control valve and timer. **Circle No. 91 on Reader Enquiry Card.**

**Physik Instrumente**

Smallest movements of less than  $0.01 \mu\text{m}$ , can be produced with piezoelectric translators manufactured by Physik Instrumente. The translators feature high positioning accuracy with a resolution of  $0.005 \mu\text{m V}^{-1}$ ; continuously variable length setting from 0 to  $40 \mu\text{m}$  per piezoelectric unit; modular construction in small units which can be combined easily with various positioning components; and fast reaction to the applied voltage with the total expansion taking place in microseconds.

Precision will not change during the lifetime of the devices due to the absence of wearing parts, and remote control makes them particularly suitable for use in automatic process control systems. Shown above are three translators being run from a Physik three-channel voltage source. **Circle No. 90 on Reader Enquiry Card.**

**Neptune**

THE Neptune European Group are exhibiting a comprehensive range of their products together with models and photographs. The principal exhibit is the Autopress, a practical and mechanically uncomplicated automatic filter press. Developed by Johnson-Progress and Moseley Rubber Company, the Autopress has a total cake discharge (press open) time of less than 3 min. Membrane Moseley plates provide filtration at up to  $15 \text{ kg per cm}^2$  and squeeze pressures of up to  $20 \text{ kg per cm}^2$ . Air-assisted cake discharge permits automation of the total press sequencing. Light safety curtains are eliminated and there are no moving parts in contact with the process liquids. Other exhibits include Glenfield industrial gate valves, the EPEX air relief valve for effluent systems, and the Neptune range of flowmeters and Tricon control instrumentation. The Neptune companies, OCP (Belgium), Hydrotec (France) and Kary (FRG), are specialists in water, waste water and sludge treatment and on exhibition will be tube settling modules, a mixed media column and a comprehensive photographic and diagrammatic display of their capabilities in the fields of Microfloc and water and waste water treatment technology. **Circle No. 89 on Reader Enquiry Card.**

**System for trace elements analyses**

## The BÜCHI Digester 445 sets new standards in sample preparation!

**Convincing advantages**

- fully automated system for the digestion of large samples
- sample weight up to 30 g
- simultaneous digestion (ashing) of 6 samples in quartz-glass flasks
- small quantities of reagents - no contamination
- no loss of trace elements during digestion
- high reproducibility
- sealed fume exhaust unit
- stepless regulation of the digestion temperature between  $150-400^\circ\text{C}$ .
- salt bath - safe and clean operation
- cooling system for exhaust tubes
- rotation of flasks

We are interested in your Digester 445. Please send us your detailed information.

**Pretema**

The 4000 seria is Pretema's third generation colour measurement system. The spectrophotometer itself satisfies all requirements of a modern spectrophotometer as regards optics, light sources, accuracy of measurement, speed, design, comfort in operation and maintenance. Matched with modern computers, with external data and program storage and input/output devices unreached in speed and comfort, and with a colour software that has grown in a 20 years' search for the best assistance to the colourist, makes it an extremely attractive system.

**Circle No. 88 on Reader Enquiry Card.**

**Huyck Fez**

The complete range of Fez woven and needled filter media will be shown atACHEMA 79. Filter fabrics for liquid filtration include special fabrics for use in filter presses, rotary drum filters or as made-up bags for candle filters. Also on show is the first fibreglass needle felt with fibreglass base fabric—Huyglas—this new filter medium will have wide application in hot gas filtration. Huyglas is designed for application in pulse jet filters and also features higher mechanical stability than has previously been achieved with glassfibre woven filter media.

**Circle No. 87 on Reader Enquiry Card.**

**Du Pont**

Chemical industry applications illustrating the total corrosion protection afforded by Du Pont's fluoroplastic and fluorinated elastomeric materials will be the feature of the company's stand atACHEMA. Most types of fluid handling equipment are now available with Teflon linings. In addition, diaphragm valves lined with thermoplastic Tefzel fluoropolymer, a material offering chemical resistance close to that of Teflon, have also come on the market. A new type of Du Pont heat exchanger known as the 'interchanger' will be exhibited atACHEMA for the first time. This development of the shell-and-tube concept takes double advantage of the chemical resistance of Teflon. One corrosive medium, such as spent sulphuric acid or phosphoric acid, flows through the tubes of Teflon, while another corrosive fluid can flow around the tubes and through the shell, which is also Teflon-lined. Heat can be transferred from one liquid to the other in either direction. Seals and similar components made of Kalrez perfluorinated elastomer will also be on show. This material combines many of the elastomeric properties of Viton with thermal stability, chemical resistance and electrical characteristics like those of Teflon.

**Circle No. 86 on Reader Enquiry Card.**

**Mastermix Engineering**

The Mastermix Mastermill is a horizontal bead mill for the high quality super fine dispersion of paints, inks, plastisols, organosols etc. It is capable of handling high viscosity materials with ease. Two versions will be on show, a 15 litre model with throughput capacity of 60 to 300 litres per h and the newly introduced 1 litre version which has been specially designed for experimental and pre-production batch work. The Mastermix Mastermill is now available in capacities of 1, 15, 30, 60 and 150 litres.

**Circle No. 85 on Reader Enquiry Card.**

**Faudi**

Standard Faudi pressure filters offer versatile combinations for applications in chemical and petrochemical processes, in the mineral oil industry, in metal working, electroplating and for corrosive, toxic, inflammable and other hazardous liquids as well as for gases, air and steam. The range features 8 sizes, 8 filter elements, 3 pressure ranges, 4 cover closures and 2 materials. A comprehensive selection of filter ratings between 1 and 1,000  $\mu\text{m}$  can be combined to cater for a wide variety of requirements. The filter elements are interchangeable and can be fully dismantled for easy cleaning.

**Circle No. 84 on Reader Enquiry Card.**

# ANIMAL OPERATING TABLE

- Sterilisable & easily cleaned
- Sturdy but lightweight for effortless handling
- Versatile design
  - table top quickly removed for use without legs
  - height and tilt adjustment for operating comfort
  - suitable for most animal sizes
  - collapsible for storage

Plus a full range of sterilisable stainless steel accessories, cleats and animal support plates. Send for details today.

**NOTE:** To keep animals warm while on the operating table we offer our Homeothermic Blanket System. Details on request.

A four-way electrical socket is fitted to one leg (home market only) plus an earth point on the underside of the table.

## A new approach in tissue culture

### PETRIPERM

a novel culture dish  
with gas permeable  
membrane as cellular  
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents.

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO<sub>2</sub> of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO<sub>2</sub>, pCO<sub>2</sub> and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

### Heraeus— CO<sub>2</sub>-Incubator B 5060 EK/CO<sub>2</sub>

## The Pendulum and Toxic Cloud

The Course of Dioxin Contamination

Thomas Whiteside

This powerful investigative report raises grave questions about the long term effects of low-level contamination of the environment by very highly toxic substances, and describes the dilatory behaviour of the United States government in taking appropriate regulatory action against such hazards, especially in view of the results of such appalling accidents as Seveso, and the defoliation of Vietnam. Simultaneous publication Cloth £10.80 Paper £3.60.

## The Kindly Fruits of the Earth

An Environmental Study of an Embryo Ecologist

G. Evelyn Hutchinson

In this charming memoir, a founder of population ecology describes his childhood, boyhood and early youth in Cambridge at a time when important discoveries and debates in science were made. This book reveals, in a hundred ways, the distinguishing feature of Hutchinson's mind: an all-embracing curiosity that moves between the scientific and the everyday in a way that illuminates both. Forthcoming £13.30

## An Introduction to Population Ecology

G. Evelyn Hutchinson

This introduction is written to appeal not only to beginners in ecology but also to an occasional historian, economist or sociologist, and those biologists in other areas of the science. £12.60

The Millipore Steritest system

### Millipore

Millipore will present at ACHEMA a comprehensive range of new, application-oriented displays in the processing, analytical and research fields. You can see at ACHEMA 79, Millipore products such as the industrial cartridge-filter series, including the new Durapore and Fluorex and Fluorogard. Millipore water purification systems combine reverse osmosis, microfiltration and ultrafiltration equipment to meet laboratory and process requirements for purified and ultrapure waters. A new 'closed system' concept for sterility testing will also be on show together with other Millipore products for particulate and microbiological analysis, ultrafiltration and fluid sterilisation.

### Hick Hargreaves & Co.

A new, skid-mounted Hick Sutorbilt blower package unit (capacities up to  $2,000 \text{ m}^3 \text{ h}^{-1}$ ) is exhibited by Hick Hargreaves. The package includes blower, motor and belt drive, inlet and outlet silencers, and optional relief valve and acoustic enclosure. The advantages offered are low price, quick delivery and easy installation. Also on display is a mimic diagram incorporating various vacuum raising products, heat exchangers and a fatty acid scrubber used on deodoriser systems. Energy conservation is demonstrated here by the recovery of heat absorbed by the cooling water in a heat exchanger and its conversion in a 'flash' vessel to low pressure heating steam.

Circle No. 81 on Reader Enquiry Card.

### G. H. Zeal Ltd

G. H. Zeal Ltd of London, makers of high quality temperature measuring, recording and controlling instruments, will be displaying a large selection of their extensive product range at ACHEMA. The emphasis of the display will be on the very popular groups of bi-metal, vapour pressure and mercury in steel actuated dial thermometers, both the new stainless steel cased heavy duty range and the 'Slim-line' series. Mercury in steel actuated chart temperature recorders will also be featured along with thermometers fitted with electric contacts and a working model of the Zeatron remote reading electronic thermometer. The recently introduced Zeatron single channel push button operated portable electronic thermometer will also be on show. The display will include a large selection of both glass and metal hydrometers, mercury and spirit filled laboratory thermometers and meteorological thermometers.

Circle No. 80 on Reader Enquiry Card.

### Newman Hattersley International

On the Newman Hattersley stand will be a selection of cast, forged and stainless steel valves, particularly suited to the European chemical industry. These include Heaton cast and forged steel gate, globe and check valves, Daytona butterfly valves and the internationally approved firesafe Heaton carbon and stainless steel ball valve. Also on display will be the Hender Bellows sealed valve which has demonstrated its atmospheric leakproof characteristics in a variety of tough environment applications. Also on the stand, Sydney Smith Dennis Ltd. will be displaying a wide range of pressure gauges in a variety of sizes and case materials to suit the varying needs of the chemical industry.

Circle No. 79 on Reader Enquiry Card.

### Volac

On view at ACHEMA is the full range of Volac volumetric glassware, disposable Pasteur and serological pipettes, Polystop reagent, dispensing and dropping bottles, and the Volac pipette plugging and de-plugging machine. John Poulten Ltd. will be introducing a range of pipetting devices, new bottles for water sampling procedures and individually packed sterilised disposable pipettes. The new Volac Micro-Pipettor is produced in capacity ranges  $0-50 \mu\text{l}$ ,  $0-100 \mu\text{l}$ ,  $0-250 \mu\text{l}$  and  $0-500 \mu\text{l}$ , each colour coded and fully adjustable in  $0.2\%$  increments, with digital capacity indication. Mk. II Volac pipette controllers feature graduated plungers, free flow control, universal push-fitting pipette attachment accepting all pipettes up to  $10.3 \text{ mm}$  diameter and robust autoclavable construction. The  $0-2 \text{ ml}$  model is an ideal instrument for use with all sizes of Pasteur pipettes. A complete range of sterilised, disposable graduated pipettes is available in six capacities from  $1 \text{ ml}$  all colour coded, supplied in sleeves of five, each pipette sealed within its own individual compartment.

two different models. The low humidity model now permits measurements between 0 and 50% RH with a precision of  $\pm 0.5\%$  RH between 0 and 10% RH, and  $\pm 2\%$  for higher humidity. The standard model takes measurements at 10–100% RH with an accuracy of  $\pm 2\%$  RH. The Hygro-skop BT is a portable electronic humidity meter which offers easy calibration and precision of  $\pm 1.5\%$  RH.  
**Circle No. 77 on Reader Enquiry Card.**

### Geho Pompen

Holthuis of Holland are represented atACHEMA '79 through their subsidiary company Geho Pompen. The company design and manufacture piston and diaphragm pumps for the feeding of filter presses, incinerators, heat treatment sludge plants, solids transportation, etc. Flow control systems designed by Holthuis permit a reduction of cycling time to 10–30% for feeding filter presses when compared with conventional diaphragm pumps. Geho pumps also allow the transportation of de-watered filter cake from centrifuges, belt presses, and so on. Further new developments are special pumps for the hydraulic transportation over large distances of material such as ore concentrates, coal slurries and industrial wastes. New developments in the field of hydraulic rapid closure systems are also shown.

**Circle No. 76 on Reader Enquiry Card.**

### Wild Heerbrugg

New products on show include the M5APO stereomicroscope which achieves the highest standards of sharpness, contrast and orthochromatism. The wide range of accessories made for the M5A will also suit the high-performance M5APO. Also on show the MPS 45 Photoautomat for macrography and photomicrography and the M520 IR image converter which provides binocular observation in the near-IR range. The new Wild Heerbrugg EB transmitted-light stand provides better conditions for the observation and photography of specimens in the transmitted light bright field and with polarisation.

**Circle No. 68 on Reader Enquiry Card.**

### Nova Werke

Nova present two new ranges of high-pressure laboratory units. (1) A mobile unit for use with liquids and gases at pressures of up to 700 bar and at temperatures of up to 350 °C. A new feature of particular interest is an electronically controlled stirring unit, the Nova Rotacontrol. (2) The new Novawiss high pressure 'equiphase' research unit has been designed specifically for visual observation of reactions under a pressure regime of up to 7,000 bar and at up to 450 K.

**Circle No. 75 on Reader Enquiry Card.**

### Polytec

Polytec have specialised in the laser field since its foundation and have produced He-Ne-lasers since 1974. The new Polytec range is made up of cylindrical laser heads all having hard sealed integral optics for long shelf life. Units from 0.5 mW to 1.5 mW have the choice of integral or separate power supplies. The model 605 with a 0.5 mW multimode output is only 40 mm in diameter and 265 mm long including power supply making it the smallest commercially available He-Ne laser.

The compact Polytec PL 605 laser

The Karlsruhe system is designed for quick determination of the distribution of particle size and particle velocity in flows of aerosols and in translucent liquids at high particle concentrations (over  $10^3$  particles per  $\text{cm}^3$ , depending on particle size). It is an ideal instrument for use in the laboratory and production: as a fast analyser for dust or power particle size distributions in dispersed state; for gas bubble distributions in transparent liquids; for periodic or sampling quality control; and as a fast measuring instrument when working with dispersed phases in gaseous or liquid flows. The modular electronic system comprises interfaces to computer, teletype, displays, tape punch and x-y plotters. The Laser-2-Focus-Velocimeter from Polytec is a compact electro-optical instrument for the precise non-intrusive, two-dimensional measurement of instantaneous velocity, flow direction and turbulence in liquid and gas flows. The velocity range is 1–2,000  $\text{m s}^{-1}$ . The instrument measures the transient time of small particles which are dispersed in the fluid between two focused laser beams. The velocimeter is not affected by background illumination. This results in high sensitivity even under adverse conditions.

### Verder

Thirty-five different pumps are now available from Verder (Deutschland) GmbH with capacities of between 0.0008 ml per min and 700 litres per hour. The new tube-type models are particularly suitable for use in liquid chromatography and in other applications requiring continuously varying liquid feeds. A new micropump model will also be introduced at theACHEMA show.

**Circle No. 73 on Reader Enquiry Card.**

Gilmont Model V water still

### Roger Gilmont Instruments

The Gilmont Instruments Model V water still delivers a product with the ultimate purity of up to 95% conductivity water quality from tap water feed. It produces this quality product at a volume of 1.5 liters per hour continuously. The Model V plugs into an ordinary 115-V a.c. receptacle, and uses a 1,000-W Vycor heater at 90% heating efficiency. An all-acrylic housing offers rigidity and protection to the all glass still. When housed, it can be used on a rolling cart, or bench mounted for fixed operation. Assembly of the still inside the housing is fast and uncomplicated due to pre-set clamp holders, Teflon sleeves and Taper-Tite nuts.

**Circle No. 72 on Reader Enquiry Card.**

### Symalit

The new Du Pont line of chemical vessel linings, Armalon, is introduced onto the European market by Symalit of Lenzburg, Switzerland. Armalon lining laminates consist of glass fabric bonded to a layer of Teflon film. The film is inert to virtually all chemicals and corrosives from  $-240\text{ }^{\circ}\text{C}$  to  $220\text{ }^{\circ}\text{C}$ . The laminates are highly resistant to de-lamination and conform well to vessel shapes. They will accept epoxy, polyester, thermo-setting and some general-purpose adhesives to form strong long-lasting bonds on existing metal vessels.

**Circle No. 71 on Reader Enquiry Card.**

### Degussa

This stand features chemicals for environmental protection (hydrogen peroxide, sodium chlorite and other oxidation chemicals, TMT 15). Catalysts made by Degussa include activated nickel; precious and non-precious metal carriers and vehicle exhaust gas catalysts. Degussa show a full range of precious metals, special metals and alloys, electrical thermometers and tantalum coatings.

## At Last! A Reliable Incubator Under \$100

### Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and  
FASEB Meetings

Dealer inquiries invited

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO<sub>2</sub>, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators. Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv resistant polycarbonate.

Multi purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only \$95. To order or for further information phone or write Billups-Rothenberg, Inc., Dept. N-1, P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

## APPOINTMENTS VACANT

### Director Chemical Research Ann Arbor, Michigan

The Pharmaceutical Research Division of Warner-Lambert is seeking an outstanding medicinal chemist to head its Department of Chemistry and lead a large team of organic, physical and analytical chemists in the exciting and demanding job of finding new and effective medicines.

Current emphasis is in the areas of Anti-infective, CNS, Cardiovascular, Anti-allergic and Immunoregulatory drugs.

The research facilities located in Ann Arbor, Michigan, are among the finest and best equipped in the world.

The successful applicant will have:

- An outstanding record of achievement in some area of medicinal chemistry, particularly in relation to the discovery of new drugs.
- A broad knowledge of medicinal chemistry as well as the research-related biological and clinical skills.
- Management and leadership skills, with abilities to encourage innovation and motivate the staff to a high level of performance.

and be responsible for:

- Ensuring a high level of scientific skills in the synthesis of potential new medicinal compounds.
- The functioning of related areas of analytical and physical chemistry.
- Some large scale preparations.

The Director of Chemistry will report to the Vice President of Preclinical Research and work closely with the Director of Pharmacology and the Director of Toxicology as well as members of the Clinical Research Group.

Join the exciting Research and Development Team at Warner-Lambert in this very key position and enjoy outstanding compensation, benefits and work environment.

Send your resume and salary history/requirements in confidence to:

Mr. D. Misner  
Personnel Supervisor  
WARNER-LAMBERT RESEARCH LABS  
2800 Plymouth Road  
Ann Arbor, Michigan 48106 U.S.A.

An Equal Opportunity Employer M/F

W165(A)

## Warner-Lambert

### UNIVERSITY OF NOTTINGHAM SCHOOL OF AGRICULTURE Sutton Bonington DEMONSTRATOR IN AGRICULTURE

Applications are invited from candidates with good honours degrees in Agriculture or appropriate Agricultural Sciences (including those who will graduate in 1979) for the post of Demonstrator in Agriculture to assist with laboratory and field classes in Crop Production. The appointment will be for a period of three years commencing September 1979 and there will be an opportunity to undertake research for submission for a higher degree.

Salary within the range £3,689 to £4,232 per annum (under review).

Further details and forms of application, returnable not later than July 6, 1979, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref: 699. 2157(A)

### UNIVERSITY OF CAMBRIDGE ANIMAL PRODUCTIVITY/ NUTRITION Applications are invited for a UNIVERSITY DEMONSTRATORSHIP

in Animal Productivity/Nutrition in the Department of Applied Biology. Qualifications—good Honours degree, research experience in some aspect of animal productivity related to nutrition and competence in biometry.

Salary in scale £4,505 to £5,591. Pensionable under U.S.S. Limited contribution to removal expenses.

Further details from and applications including full personal particulars, list of publications and names and addresses of not more than three referees to the Secretary, Faculty of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, not later than July 6, 1979. 2159(A)

### UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGY Applications are invited for TWO RESEARCH TECHNICIAN POSTS

in a group supported by a 5-year M.R.C. grant and working on the role of 5HT in the brain. Experience in neurochemistry, pharmacology or the study of behaviour is an advantage, but not essential.

Salary £2,915 to £3,779 (including London Weighting).

Curriculum vitae and names of two referees to Professor G. Curzon, Department of Neurochemistry, 33 Johns Mews, London WC1N 2NS. 2087(A)

### UNIVERSITY OF CAMBRIDGE DEPARTMENT OF CLINICAL BIOCHEMISTRY School of Clinical Medicine Hills Road A GRADUATE

#### RESEARCH ASSISTANTS

is available in the above Department from August 1, 1979. The post is supported by a grant from the Wellcome Trust and is funded September 1981 with a possible extension for a further two years.

The starting salary is £3,961.

The project involves the purification and immunoassay of human specific proteins and the application of such measurements to clinical problems.

For further details contact Prof. C. N. Hales, Department of Clinical Biochemistry, University of Cambridge Clinical School, Addenbrooke's Hospital, Hills Road, Cambridge.

Closing date for application, July 2160

### THE HANNAH RESEARCH INSTITUTE (for studies relating to the production and utilisation of NUTRITIONIST

There is a vacancy in the Nutrition and Metabolism Section of the Animal Studies Department for a person to undertake work on the energy metabolism of farm animals. The successful applicant will take charge of animal calorimeters and will be responsible for the conduct of section's calorimetric experiments.

The appointment will be made at Scientific Officer level, for minimum qualifications are a 1st in an appropriate subject (Agriculture, Nutrition, Agricultural Science, Biology, Biochemistry or Chemistry H.N.C. with appropriate experience).

The salary (under review) is £4,415, and there is a contributory pension scheme.

Requests for further details should be addressed to:

The Secretary,  
The Hannah Research Institute,  
Ayr KA6 5HL.

Applications close on July 6, Ref: HRI 33. 2162

### PRE AND POSTDOCTORAL POSITIONS

are available for individuals with microbiology background for studying the protein synthesising system with special emphasis on ribosome biogenesis, biogenesis and function. Teaching opportunities are available. Reply with résumé to: Dr Bruce Sells, Professor and Director, Laboratories of Molecular Biology, Faculty of Medicine, Health Sciences Centre, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X6, Canada. W163

**UNIVERSITY OF  
LIVERPOOL  
DEPARTMENT OF  
OCEANOGRAPHY  
POSTDOCTORAL SENIOR  
RESEARCH ASSISTANT**

Applications are invited for the post of Senior Research Assistant in connection with a survey of trace metals to be carried out in the Mersey estuary. Candidates should possess a Ph.D. in analytical chemistry, marine chemistry, or a related subject. The project is sponsored for three years by the North West Water Authority. The initial salary will be either £4,232 or £4,505 per annum. Applications, together with the names of three referees, should be received not later than July 7, 1979, by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/635/N. 2104(A)

**UNIVERSITY OF  
LIVERPOOL  
DEPARTMENT OF  
BIOCHEMISTRY  
RESEARCH ASSISTANTS**

Applications are invited from graduates in Biochemistry or related subjects to work on projects investigating (a) the turnover of specific proteins normal and abnormal muscle. The project is funded for three years by the MRC; and (b) the regulation of protein breakdown in muscular dystrophy. The project is funded for three years by the Muscular Dystrophy Group of Great Britain. The posts are under the supervision of Dr. R. J. Beynon and applicants with an upper second or first class honours degree will be considered as candidates for a Ph.D. The posts are tenable from October 1979 at an initial salary of £3,689 per annum. Applications, together with the names of three referees should be received not later than July 6, 1979, by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/639 (a) or /N. 2106(A)

**UNIVERSITY OF  
EDINBURGH  
TECHNICIAN**

Required for the DEPARTMENT OF GENETICS, Kings Buildings, to join a team working on the cellular molecular biology of eye tissues. Experience in at least one of the following techniques required: cell culture, molecular biology, enzyme assays, electrophoretic separation techniques. Further training will be given if needed. This appointment is supported by the Medical Research Council and will be for a period of 3 years. Salary on the scale £3,474 to £5,616 p.a. Applications should include names and addresses of two referees. REF: NS202. Application forms for the above post can be obtained from the Personnel Office, University of Edinburgh, 63 Leith Bridge, Edinburgh EH1 1LS. 031-556-2930. 2119(A)

**LEGUME AGRONOMIST/  
BACTERIOLOGIST**

to participate in international field experiments to assess yield response of legume crops to inoculation with *Rhizobium*. Ph.D. in legume agronomy, physiology or bacteriology required. Must be prepared to travel extensively and have previous field experience with tropical legumes, and legume inoculants. Demonstrated ability to work on multi disciplinary projects would be an advantage. Application to: Dr. Jakek Halliday, NITFAL, c/o University of Hawaii, P.O. Box 100, Paia, Hawaii 96779. The University of Hawaii is an EEO/AA Employer. W159(A)

**ROTHAMSTED  
EXPERIMENTAL STATION  
Harpden, Herts. AL5 2JQ  
MOLECULAR BIOLOGIST**

There is a vacancy for a molecular biologist with experience in nucleic acid technique to join a team in the Biochemistry Department working on the genes specifying the cereal storage proteins. This team is part of a new programme within the Agricultural Research Service concerned with understanding and manipulating of plant genes.

Qualifications: First or Upper Second Class Honours Degree in Biochemistry or related subject with a minimum of two years' relevant postgraduate research experience. Preference given to candidate with a Ph.D. degree. The appointment will be for three years in the first instance.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448. (Pay Award pending.) Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 366 by June 29, 1979. Further details on request. 2114(A)

**ROTHAMSTED  
EXPERIMENTAL STATION  
Harpden, Herts. AL5 2JQ**

STATISTICIAN required to work on problems of applied multivariate statistics. The successful candidate will be expected to assist in developing new methodology, to recognise new problems and to apply newly-developed methods, as well as well-established ones, to the analysis of multivariate data. A high level of research ability is sought. Applications will necessitate the use of computers, often using the Genstat statistical package, but will also require the writing of new programs, for which a sound knowledge of modern numerical techniques is essential. The post involves some consulting work, especially with soil scientists.

Minimum qualifications: 1st or upper 2nd class honours degree in mathematics or statistics, and preferably a higher degree or equivalent post-graduate experience in a relevant field. An interest in applied multivariate analysis is desirable.

Appointment in grade of Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) (Pay Award pending). At least two years' relevant post qualifying experience is required for appointment as HSO. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 397 by June 29, 1979. Further details on request. 2115(A)

**THE LONDON HOSPITAL  
MEDICAL COLLEGE  
(University of London)  
DEPARTMENT OF  
HAEMATOLOGY**

Applications are invited for the post of

**TECHNICAL ASSISTANT**

in the Serology Unit of the Department of Haematology. Candidates should hold appropriate University or I.L.M.S. qualifications or equivalent.

The post comprises forensic serology, both paternity tests and investigation of stains.

Previous experience in blood group serology and/or electrophoretic techniques preferred.

Salary according to age and experience on Whitley Council Scale within the range £3,615 to £6,123 per annum, including London Weighting (currently under review). Four weeks' annual holiday, plus extra days when College is closed.

Further details from Professor Barbara Dodd, 01-247 5454, ext. 360.

Applications in writing to The Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, quoting Reference No. SUH6/79. 2095(A)

**CSIRO AUSTRALIA**  
**Division of Materials  
Science Production  
Technology Laboratory  
Woodville South Australia**

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

**General:** The Division of Materials Science is engaged in broad areas at Catalysis and Surface Science, Engineering Ceramics and Refractories and Production Technology. It operates laboratories at Parkville, Fitzroy and Fisherman's Bend in Victoria and at Woodville in South Australia. The Production Technology Laboratory, Adelaide has a total staff of approximately 50 people and is a major component of the Division's programs. There are good metallurgical support and computing facilities available. Pilot plant facilities are being established for research into the production of metallic components by a variety of techniques including casting, welding, forging and machining. All research staff are encouraged to sit on liaison committees and to maintain close contacts with manufacturing industry around Australia.

**Position No. 1—Ref. No. 370/350,  
Postdoctoral Research Fellow  
(Materials Science)**

**Duties:** To initiate and develop research projects concerned with the control of the structure of surface coatings applied for protection against wear or corrosion. Experimental equipment available for the projects is an R.F.-D.C. sputter-etch coating unit, a plasma spray unit and various vapour coating units. Current research interests extend also to the morphology and mechanisms of degradation of zinc-rich paints for corrosion control.

**Qualifications:** PhD degree or equivalent in Materials Science. Experience in the structure and properties of coatings applied to metallic components or cutting tools.

**Salary:** Within the range of: Research Scientist \$15,422—\$18,904 or Senior Research Scientist \$19,572—\$22,405 pa.

**Tenure:** This appointment is for a fixed term of 5 years. Superannuation is available.

**Position No. 2—Ref. No. 370/349,  
Production Engineer  
(Metal Forming)**

**Duties:** Leader of an interdisciplinary team concerned with metal forming, particularly with forging of ferrous components. Current emphasis of the research centres on experimental and theoretical analysis of billet deformation and die design. The objective is to reduce production costs in forging by simplifying the production process and reducing the extent of finishing required on forged components.

**Qualifications:** An experienced mechanical or manufacturing engineer is required with PhD qualifications or equivalent, and preferably with a background of mission-oriented research of relevance to manufacturing industry. The appointee should have mathematical ability and experience in computer modelling of deformation processes.

**Salary:** Within the range of: Senior Research Scientist A\$19,572—A\$22,405 pa. Principal Research Scientist A\$23,247—A\$26,368 pa.

**Tenure:** Indefinite appointment with superannuation.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the appropriate reference number(s) should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by 21st July, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue N.W., Washington D.C. 20036.

2149(A)

PHLS Centre for Applied Microbiology and Research, Porton, Salisbury

A vacancy exists for a

## Senior Grade Microbiologist

to co-ordinate the scientific work of the Animal House in the Centre. He/she will be responsible to the veterinary surgeon in charge of animal facilities. The animal complex is large, and its functions include the supply of laboratory animals for the research programme of the Centre and the maintenance of primates and other animals experimentally infected with a variety of pathogenic micro-organisms.

Applicants must hold a science degree and have at least four years' postgraduate experience. In addition a qualification in animal technology, e.g. F.I.A.T. is desirable. Applicants should also have considerable experience in the scientific work in an animal house and in particular the containment of pathogens.

Salary: Senior Grade Microbiologist £5,451 to £6,837. N.H.S. terms and conditions of service.

Further details of the post can be obtained from Dr A. Baskerville (Tel. 0980-610391).

Applications stating date of birth, qualifications, experience and publications and naming three referees should be sent to Mrs M. Bushby, C.A.M.R., Porton Down, Salisbury, Wilts. SP4 0JG. 2137(A)

**PHLS**

Public Health Laboratory Service Board.

Cambridge Area Health Authority (T)

### Addenbrooke's Hospital Cambridge

Department of Clinical Biochemistry,  
Cambridge University

## Basic Grade Biochemist

Applications are invited for the above N.H.S. post. Applicants should have a good honours degree in Biochemistry, Chemistry or the equivalent. The possession of some post graduate experience of clinical biochemistry or a Ph.D. in a relevant field will be an advantage.

The department is a joint University/NHS laboratory and encourages research for which there are excellent facilities. Research interests include diabetes, immunoassay, biochemistry of membranes and tissue-specific proteins. The laboratory provides diagnostic services for all the Cambridge hospitals and acts as a regional centre including the East Anglian Regional Hormone Assay Service.

The appointment will provide further training and experience in clinical biochemistry and the opportunity to carry out research. Study for higher qualifications will be encouraged.

Whitley Council conditions apply. Salary scale (under review): Probationary £3,486 (min.); Post Probationary £3,798 (min.) to £4,899 (depending on experience). N.H.S. superannuation.

Application forms and further particulars may be obtained from Professor C. N. Hales, Department of Clinical Biochemistry, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QR. Closing date 27th July. 2074(A)

## THE HANNAH RESEARCH INSTITUTE

FOR STUDIES RELATING TO THE PRODUCTION  
AND UTILISATION OF MILK

### HEAD OF THE BIOCHEMISTRY DEPARTMENT

Applications are invited for the above post. Applicants should have a considerable research experience in animal or microbial biochemistry supported by publications in scientific journals. Preference may be given to persons with a specialist interest in the energy metabolism of the mammary gland.

The post will carry responsibility for the co-ordination and direction of current research into the lipid metabolism of the tissues of ruminant the degradation in the rumen of the structural constituents of herbage and the regulation of microbial metabolism in the rumen, and for the initiation of new work.

Appointment will be in the Senior Principal Scientific Officer grade salary range £11,449 to £12,882 (from August 1, 1979). A non-contributory pension scheme is operating.

Further particulars may be obtained from The Secretary, Hannah Research Institute, Ayr KA6 5HL, to whom applications, giving a curriculum vitae, list of publications and the names of three referees should be forwarded by July 20, 1979. Ref. HRI 35. 2161(A)

## UNIVERSITY OF EAST ANGLIA

Norwich

SCHOOL OF CHEMICAL SCIENCES

ELECTRON ENERGY LOSS

SPECTROSCOPY

OF ADSORBED MOLECULES

Applications are invited for an

S.R.C. POSTDOCTORAL

RESEARCH APPOINTMENT

to work with this new highly sensitive technique of vibrational spectroscopy in order to study the structure of chemisorbed species on single-crystal planes of metals. Such measurements will be made in conjunction with a range of other surface analytical techniques. Experience in the application of electron spectroscopic techniques in surface chemical physics would be of advantage.

The project is a joint one between East Anglia and Queen Mary College, London (Professor J. Pritchard) but the successful applicant will be based at Norwich. The post is tenable for a period close to 3 years depending on the initial salary which will be near point 3 of the RA1A scale (£4,776).

Applicants should write to Professor N. Sheppard, FRSC, or Dr M. A. Chesters, School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ, enclosing a curriculum vitae and the names and addresses of two referees. 2155(A)

## ROTHAMSTED

EXPERIMENTAL STATION

Harpden, Herts. AL5 2JQ

Applications are invited from suitably qualified scientists for the post of

HEAD

OF THE SOIL MICROBIOLOGY

DEPARTMENT

to succeed Dr P. S. Nutman, FRSC, who retires in Autumn 1979.

The Soil Microbiology Department has over 20 scientific staff and receives many visitors. The scientist appointed will be expected to lead actively the study of soil micro-organisms of agricultural significance and to develop this research in collaboration with other relevant disciplines at Rothamsted.

Appointment in the grade of S.P.S.O., £11,449 by 2 increments to a maximum of £12,882. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 378 by July 20, 1979. Further details on request. 2163(A)

## UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGICAL GRADUATE

RESEARCH ASSISTANT

required to work with a research in a study of effects of neurochemicals on metabolic properties of the axon. Histochemical, biochem and autoradiographic methods will principally be used. Post is suitable recent honours graduate (1 or 2) zoology, physiology or similar subject and the work could be used to gaining a higher degree.

The post is supported by a year grant from Action Research the Crippled Child at a starting of £4,218 (including London allowance).

Applications with curriculum and names of two referees to Prof J. B. Cavanagh, Institute of Neurology, the National Hospital, Queen's Square, London WC1N 3BG. 2085

## ROYAL POSTGRADUATE MEDICAL SCHOOL

University of London

DEPARTMENT OF

CLINICAL PHARMACOLOGY

JUNIOR TECHNICIAN

required to join a team working on isolation and characterisation of different forms of cytochrome from human tissues. The appointed will be trained to enzyme kinetics using a variety of chemical and biochemical techniques including GLC and HPLC. The is supported by a three-year grant from the Medical Research Council.

The successful candidate must possess an O.N.C. or equivalent appropriate subject.

Salary up to £3,138 a year.

Application forms and further particulars may be obtained from Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS, quoting reference number 20/MRC. 2083

**AUSTRALIAN NATIONAL  
UNIVERSITY  
RESEARCH SCHOOL OF  
CHEMISTRY  
RESEARCH FELLOWS**

Applications are invited for appointment as Postdoctoral Research Fellow in the Research School of Chemistry. Appointments will be for two or three years and may be made in any area of chemistry. Current major research interests in the School are—

**Organic Chemistry:** (Professor A. J. Birch, Mr R. W. Rickards, Dr J. K. MacLeod, Dr L. N. Mander): including organic chemistry of biologically active compounds; synthetic organic chemistry; organometallic chemistry in organic synthesis; metal-ligand reduction studies.

**Inorganic Chemistry:** (Professor G. Hyde, Professor A. M. Sargeant, Dr M. A. Bennett, Dr S. B. Wild (to arrive)): including solid state inorganic chemistry; synthesis, structure and reaction mechanisms of transition metal complexes; biometallic chemistry; organo-transition metal chemistry and chiral arsesines and phosphines.

**Physical and Theoretical Chemistry:** (Professor D. P. Craig, Dr J. Ferguson, Dr R. Bramley, Dr T. R. Elberry): including molecular and crystal theory; spectroscopy and photochemistry; photophysics; disordered materials.

**Theoretical Organic Chemistry:** Dr Radon.

**Mass Spectrometry:** Dr J. K. MacLeod: organic and biological applications; ICR spectrometry.

**X-ray Crystallography:** Dr G. B. Robertson.

**Analytical Chemistry:** Miss B. J. Svenson.

Appointments will be made primarily within these research groups, but proposals for independent research in areas which complement existing programmes will also be considered.

The School is non-departmental and is well equipped to contemporary standards.

Salary on appointment will be in accordance with qualifications and experience within the range \$A15,786–\$A20,606 per annum. Current exchange rates \$A1 : UK£0.53p : S1.10.

Reasonable travel expenses are paid and assistance with housing is given to an appointee from outside Canberra. Superannuation benefits are available.

The University reserves the right to make an appointment or to make an appointment by invitation at any time.

Further information obtainable from the Association of Commonwealth Universities (Apsus), 36

London Square, London WC1H 0PF. There is no application form.

Applicants should supply to the Registrar of the University, P.O. Box Canberra, A.C.T., Australia, by August 31, 1979 a curriculum vitae, of publications and statement of research interests, together with two

port-sized photographs, the names and addresses of three academic referees and the probable date on which a Postdoctoral Research Fellowship, if awarded, could be taken up.

**ANTHONY NOLAN  
BONE MARROW  
RESEARCH LABORATORIES  
St. Mary Abbots Hospital  
Harlow Road, London W8  
SENIOR GRADE PERSON**

needed to take technical and partial administrative charge of these laboratories mainly responsible for tissue culture bone marrow volunteer donors. Applicant should be graduate or senior scientist and have higher qualifications. Considerable experience in tissue culture essential. Apply in writing to Dr C.O. James, Blood Transfusion Westminster Hospital, Dean Ryle, London SW1. 2110(A)

**AGRICULTURAL  
RESEARCH COUNCIL  
INSTITUTE OF  
ANIMAL PHYSIOLOGY  
Babraham, Cambridge CB2 4AT**

Applications are invited from

**GRADUATES**

in Biochemistry or Cell Biology to join a small research group interested in the regulation of ovarian function in mammals. The officer will be involved in a wide range of biological experiments including tissue culture, membrane function, radioimmunoassay of steroid hormones and characterisation of proteins.

Salary in Scientific Officer scale, at present £2,839 to £4,415 per annum, but will be subject to the 1979 Civil Service pay review according to qualifications and experience. Applicants should have, or be expected to graduate with, a pass degree, H.N.C. or equivalent in the relevant biological science. Non-contributory superannuation scheme.

Application form and further details may be obtained from the Secretary of the Institute, quote reference AR521. Closing date: June 28, 1979. 2166(A)

**PAPANICOLAOU  
CANCER RESEARCH  
INSTITUTE**

Applications are invited for

**POSTDOCTORAL**

**RESEARCH ASSOCIATES**

to work with Dr F. Ahmad on (a) isolation, characterisation and control properties of enzymes involved in fatty acid metabolism in bacteria and (b) to work on a neurochemical project involving identification and eventual characterisation of a number of enzymes considered to be present in central nervous system myelin, e.g., protein kinase(s) and phosphoprotein phosphatase(s).

Applications, which should include a curriculum vitae and the names and addresses of three referees, should be sent by August 1, 1979, to Dr F. Ahmad, P.O. Box 016188, Miami, Florida, 33101, USA, from whom further particulars may be obtained. We are an equal opportunity employer. W170(A)

(University of London)

**RESEARCH**

**DEMONSTRATORSHIP IN  
PLANT PATHOLOGY**

Applications are invited for a College Research Demonstratorship, available for a 3-year period in the Department of Biology, from October 1979. The Demonstrator will be required to register for a higher degree of the University of London and to conduct research on physiological/biochemical aspects of the resistance of carrot root tissue to *Botrytis cinerea* under the supervision of Dr J. B. Heale.

The Demonstrator will receive a maintenance award of £2,250 per annum if living away from home and £1,370 per annum if living at home plus paid demonstrating (up to 150 hours per year). All fees are also met.

Applicants should have, or expect to obtain a minimum of an upper second class Honours degree in Biochemistry, Botany, Microbiology or related subject, and should write to Dr J. B. Heale (from whom further particulars are available), Biology Department, Queen Elizabeth College, Campden Hill, London W8 7AH, enclosing a curriculum vitae and the names of 2 academic referees. Closing date: June 25, 1979. 2088(A)

**CSIRO AUSTRALIA**  
**Chief of Division**  
**Institute of Physical Sciences**  
**Division of Applied Physics**  
**Sydney, NSW**

Applications are invited for the position of Chief, Division of Applied Physics, from scientists who have an established record of personal research achievement and leadership in an appropriate field of science.

CSIRO is Australia's largest and most comprehensive research organization, having approximately 7,000 employees of whom 2,400 are research and professional scientists. Its broad charter covers research into problems of primary and secondary industries and also such fields of community interest as human nutrition, the environment and the development and use of natural resources. The Organization has recently grouped its research activities in five Institutes and the Division of Applied Physics is one of the Divisions within the Institute of Physical Sciences. Other Divisions in the Institute are Atmospheric Physics, Chemical Physics, Cloud Physics, Computing Research, Environmental Mechanics, Materials Science, Mathematics and Statistics, Radiophysics and the Australian Numerical Meteorology Research Centre.

The Division of Applied Physics is located at Lindfield, a suburb of Sydney, in the new National Measurement Laboratory which was opened in February 1979. In addition there are branch laboratories in Adelaide and Melbourne.

The position of Chief will become vacant upon the retirement of the present incumbent in August 1979. The total staff of the Division is 410 which includes some 160 professional scientists.

The objectives of the Division are:

To establish and maintain the Australian legal standards of measurement as required by the Weights and Measures (National Standards) Act, together with the standards for basic and other physical quantities of importance to Australia.

To promote, together with other national organizations such as National Association of Testing Authorities, and Standards Association of Australia, the development of calibration and other arrangements to enable the community to base its measurements on these standards.

To undertake applied research of importance to industry and the community, utilizing the skills and resources of the Division and to collaborate with industry in exploiting promising developments.

To undertake appropriate physical research utilizing the skills and resources available in the Division.

To undertake any scientific and industrial research that the Executive sees as appropriate for the Division.

To give advice and assistance to industry and the community in areas where the Division has special competence and to provide courses of training where appropriate.

To participate in international scientific and technological activities, especially those arising from Australia's obligations under the Metric Treaty.

To support and co-operate with other nations establishing their own standards and measurement facilities.

A Chief of a Division is responsible for the leadership, development, scientific direction and integration of the research programs of the Division, and is encouraged to promote active collaboration with other Divisions, industry and research bodies working in associated areas. A recent review of the work of the Division of Applied Physics pointed to the need for the Division to improve collaboration with other CSIRO Divisions, industry, and universities. The Chief will be expected to give attention to this aspect of the Division's activities.

The salary for the position is negotiable but will not be less than \$A34,374 pa.

Appointment to the Organization is for an indefinite period and carries Commonwealth Superannuation privileges subject to normal conditions. The position of Chief is offered for a negotiable term of the order of seven years, with subsequent options for a further term, if mutually desired, or for a senior position in the Organization.

Further information on the Division is in a booklet available on request from the Secretary, CSIRO at the address below.

Dr W J McG Tegtart, a member of the Executive of CSIRO, would be pleased to discuss the position with potential applicants. He would also be pleased to receive advice concerning this appointment from people with a particular interest in it. Dr Tegtart can be contacted at the address below.

Applications stating full personal and professional names of at least two professional referees and quoting number 750/762 should reach the Secretary by 14 July, following address: The Secretary, CSIRO, PO Box 225, Dickson ACT 2602, AUSTRALIA.

## VG Scientific Limited

VG Scientific manufactures a range of highly sophisticated electron spectrometers. Due to the success of these products, particularly in the export market, we urgently require more personnel. Vacancies are available for

### Physicists, Engineers and Technicians

with experience in electronics or electron spectrometry. A starting salary in the range £3,500 to £7,000 is envisaged. Usual successful company benefits. Please write or telephone for an application form:

## DIRECTOR OF THE ARC

**Meat Research Institute**  
**Langford, Bristol BS18 7DY**

The Agricultural Research Council invites applications for the Post of Director of the Meat Research Institute which will become vacant on August 31, 1979 as a result of the resignation of the present Director, Professor J. R. Norris, to take up a post in Industry.

The Institute is concerned with applied research to meet the needs of the consumer and the meat industry. In addition it conducts a substantial programme of more fundamental work in animal physiology, muscle structure and biochemistry, together with aspects of food science including microbiology, biophysics and meat flavour.

Candidates should have qualifications or equivalent experience in one or more of the disciplines encompassed by the above description together with a substantial record of research and proven ability in the conduct and management of research.

The post is graded Deputy Chief Scientific Officer, the initial point on the salary scale being £12,773 rising by two annual increments to £13,631. On August 1, 1979 the scale will be £13,359 rising by two increments to £14,128 and on April 1, 1980 to £13,359 rising by two increments to £14,372. There is a non-contributory superannuation scheme. Closing date for applications is July 10, 1979.

Further particulars and application forms may be obtained from Dr Gareth M. Price, Agricultural Research Council, 160 Great Portland Street, London W1N 6DT. 2082(A)

### UNIVERSITY OF DUNDEE DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a  
**POSTDOCTORAL  
 BIOCHEMIST**

Required to work with Dr Grahame Hardie on a project sponsored by the Medical Research Council. The investigation is concerned with the structure of mammalian fatty acid synthase, an enzyme which has seven active sites on a single polypeptide chain (see FEBS Letters (1978) 94, 33-37). Experience in enzymology and/or protein chemistry will be an advantage. The appointment is for one year initially, renewable for a further two years, with starting salary on Range 1A (up to £4,776, under review). Applications, with curriculum vitae, names of two referees, and an indication of date of availability, should be sent to The Secretary, The University, Dundee DD1 4HN by July 6, 1979. Please quote Reference EST/60/79J. 2102(A)

A POSTDOCTORAL SCIENTIST is required to fill a vacancy in the Radiotherapy Research Department of the Institute of Cancer Research. The work of the Department involves the study of the biological effects of radiation and cytotoxic drugs on mouse tumours, human tumours, and human tumour xenografts, making use of tissue culture techniques to assess *in vitro* cell cloning techniques for the direct testing of chemosensitivity in human tumours and familiarity with tissue culture and pharmacology would be an advantage. The appointment will be for an initial period of 3 years, with a possibility of extension. Salary in range £3,909 to £5,129 per annum plus London Allowance of £502 per annum. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting Ref. 300/G/7. 2090(A)

### IMPERIAL CANCER RESEARCH FUND TECHNICIAN/RESEARCH OFFICER

(1) Required in our new Cytogenetics Laboratory to assist with analysing and identifying the human chromosomes in human/mouse somatic cell hybrids. Experience of human metaphase chromosomes, preparation of spreads and standard banding techniques useful. (Reference ES1).

(2) Required to assist with biochemical and immunological assays on somatic cell hybrids for various enzymes, types of collagen and complement components. Experience in a range of biochemical and immunological techniques essential. (Reference ES2).

H.N.C./Degree essential. Salary range £3,615 to £5,256. For further information and application form write or telephone, quoting above reference, to Miss Maddex, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2, on 01-242 0200, ext. 305. 2129(A)

### ULSTER: THE NEW UNIVERSITY SCHOOL OF BIOLOGICAL AND ENVIRONMENTAL STUDIES

**S.R.C. Postgraduate  
 Research Studentship**

Applications are invited from persons who hold or expect to hold a good honours degree in an appropriate subject for a studentship to carry out research in one of the following areas:—

1. Anaplerotic carbon fixation by germinating seeds. (Dr A. M. Flinn.)

2. Gastropod Biology—A range of topics are available including those of pheromonal influences on slug behaviour, the water economy of slugs and its relationship to behaviour and the organisation of the defensive responses of slugs and snails. (Dr T. Cook.)

3. Comparative light and electron microscopic studies of coremium formation in the basidiomycete *Pleurotus cystidiosus* compared with morphologically similar ascomycetous forms. (Dr R. T. Moore.)

Applications, giving an indication of the preferred research topic and the names of two academic referees, should be sent at once to The Registrar, The New University of Ulster, Coleraine, N. Ireland BT52 1SA. Ref: 79/49. 2146(A)

### THE UNIVERSITY OF LEE DEPARTMENT OF PHYSICS

Applications are invited from suitable qualified candidates for a temporary post of

#### RESEARCH FELLOW

in the above Department under the auspices of the I.C.I. Joint Research Scheme. The successful applicant would undertake research, under the direction of Professor I. M. Ward, molecular conformations and orientation in oriented polymers, working on an active research group studying properties and microstructure of polymers. The appointment will be made for a fixed period of three years.

Salary on the 1A scale for Research and Analogous Staff £4,333 to £7,500 (under review), according to qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS1 9JT, quoting reference number 52/6/79. Closing date for applications: July 1979. 2156(A)

***Head of Regulatory Affairs***  
***five figure salary + car***

This is a new senior appointment, offering international scope, in the Medical & Development Division of Glaxo Group Research Limited at Greenford, Middlesex. The successful candidate will be responsible at Director level for the successful operation of the three Departments concerned with registration, re-registration and control, both in the UK and overseas, of all products developed from laboratory research at Greenford and at Ware, Herts.

We are looking for a candidate, with an academic or industrial background, prepared to inform himself/herself on all aspects of regulatory affairs, and who will represent the Company often with other senior scientists or physicians at meetings with Registration Authorities worldwide. Applications are in-

vited from established physicians or scientists with biological knowledge, who should be at least 35 years of age. They should be capable organisers with the ability to ensure that our submissions to Regulatory Authorities are scientifically correct.

The commencing salary should prove attractive to candidates earning around £10,000 per annum. Other benefits include a non-contributory Pension Scheme, participation in the Group's profitability and generous relocation expenses where appropriate.

Please write, giving details of qualifications and relevant experience, to: Personnel Manager, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex, quoting reference number /267.

2150(A)

Glaxo Group Research Ltd.

UNIVERSITY OF OXFORD  
DEPARTMENT OF  
GEOLOGY AND MINERALOGY  
RESEARCH ASSISTANT  
IN PALAEOZOOLOGY

**Research Assistant** at either Pre-Postdoctoral level is required for period of up to two years to work under the direction of Dr W. J. J. nedy on the evolution and biogeography of European late Cretaceous ammonite faunas. Candidates should either have, or expect to gain, an Honours Degree (in the case of Predoctoral candidates) or have held their doctorates (in the case of Postdoctoral candidates). Starting salary will be in the range £3,689 to £7,100, depending on age and experience, plus U.S.S. benefits.

applications together with the  
es of two referees, should be  
mitted not later than **June 23,**  
to Dr W. J. Kennedy, Depart-  
s of Geology and Mineralogy,  
s Road, Oxford OX1 3PR, from  
m further particulars may be  
ined. 2130(A)

KENYATTA  
UNIVERSITY COLLEGE  
KENYA

Applications are invited for the following posts in the DEPARTMENT OF CHEMISTRY:-

**1. LECTURER IN PHYSICAL CHEMISTRY.** Applicants must have a good first degree in Chemistry and a Ph.D. in some branch of Physical Chemistry. University teaching experience at the undergraduate and post-graduate levels, and experience in Teacher Education will be considered advantageous. The appointee will be expected to teach Physical Chemistry to undergraduate and M.Sc. students, and to carry out research in some branch of Physical Chemistry.

**2. LECTURER IN INORGANIC CHEMISTRY.** Applicants should hold a good basic degree in Chemistry together with a Ph.D. in Inorganic Chemistry. Experience in Teacher Education would be advantageous. The appointee will be required to teach in the B.Ed. and M.Sc. programmes and carry out research in some field of Inorganic Chemistry.

Salary scales: K£2,016 to 3,312 p.a., (K£1 sterling = £1.28). The British Government may supplement salary in range £4,278 to 4,818 p.a. (sterling) for married appointee or £2,730 to 3,156 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages: subsidized housing; S.S.S.F. or F.S.S.U.: non-contributory medical aid scheme. Detailed applications (2 copies) with curriculum vitae and naming 3 referees should be sent by airmail to the Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya by July 27, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0BD. Further details may be obtained from either address. 2154(A).

**NEWHOUSE, LANARKSHIRE**

# PROGRAMMER

Applications are invited for the above post which has arisen due to expansion of activities in the Automation Unit within the Scientific Development Group of Organon Laboratories Ltd.

The Automation Unit is responsible for providing computing facilities including on-line data capture, statistical analyses and a data-base management system for Chemists and Biologists engaged in research into the development of new drugs. The Automation Unit uses primarily a small network of PDP-11 computers under an RT11/Remote-11 operating system.

The person appointed will assist the Group Leader in the day to day management of these facilities and duties will include writing programmes in FORTRAN. Some experience of scientific programming and PDP-11 computers would therefore be an advantage.

Organon Laboratories Ltd. is located at Newhouse which is situated on the M8 Glasgow-Edinburgh road. Conditions of employment are in keeping with the best modern practice and include salary commensurate with age and experience, Bonus, Sick Pay, Permanent Health Insurance, Pension and Life Assurance Schemes.

Written applications giving details of age, present salary, qualifications and experience to date should be addressed for the attention of the Personnel Manager, Organon Laboratories Ltd., Newhouse, Lanarkshire, ML1 5SH.

2076(A)

UNIVERSITY OF OXFORD  
UNIVERSITY  
LECTURESHIP  
IN FORESTRY

Applications are invited for the post from candidates in the field of aviculture. The salary will be according to age on the scale £4,232 to £6,000 p.a. Details may be obtained from the Administrator, Department of Agriculture, South Parks Road, Oxford OX1 3RB, to whom completed applications (one typed copy) should be sent by 30. 1979. 2078(A)

# Cell Biologist

We are interested in recruiting an innovative post-doctoral research scientist, aged between 25 and 30, to work in our Cell Biology Department. An interest in cell culture techniques in general and their application to the fields of inflammation and rheumatic diseases is desirable. The successful appointee will form part of a multi-disciplinary project group and will be expected to interact with members of the Chemistry, Pharmacology and Biochemistry Departments. He/she will have day to day responsibility for three graduates and technical staff working in our modern laboratories in Welwyn Garden City.

Roche Products Limited is part of a major international pharmaceutical Company based in Switzerland and is itself one of the leaders in the industry in the United Kingdom. The salary payable for this new post will be commensurate with experience and assistance with relocation expenses may be offered where appropriate.

If you are interested in applying for this post then please write or telephone Welwyn Garden City 28128 quoting reference RH6 and giving brief details of your career to Mr J. G. Bennett, Personnel Manager, Roche Products Limited, PO Box 8 Welwyn Garden City, Herts AL7 3AY.

2151(A)

**ROCHE**

## JOHN INNES INSTITUTE DEPARTMENT OF APPLIED GENETICS Three-year temporary appointment BIOCHEMIST/ MOLECULAR BIOLOGIST

required to join a group studying the organisation and expression of the plant genome. The work will involve the isolation and characterisation of a particular nuclear fraction as well as the characterisation of organelle DNA; although the group's work will continue, this particular aspect is expected to be completed by the end of the three year period. The post offers considerable scope for a person interested in the analysis of DNA by a variety of techniques. Further particulars may be obtained from Professor D. Roy Davies.

Applicants should have first or upper second class honours degree in biochemistry or appropriate subject, with at least two years' experience in a relevant field. Appointment as Higher Scientific Officer (£4,101 to £5,448 per annum) (salary under review). Starting salary depending on experience. Non-contributory superannuation.

Applications, quoting reference AG/39, giving full particulars and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich NR4 7UH, not later than July 12, 1979. 2111(A)

## WOLFSON UNIT OF CHEMICAL ENTOMOLOGY University of Southampton DEPARTMENT OF CHEMISTRY Applications are invited for the post of RESEARCH ASSISTANT

in the Wolfson Unit of Chemical Entomology from October 1, 1979. The unit is mainly concerned with the development of new methods for insect control and the major duty of the research assistant will be organic synthesis of biologically active compounds. In addition to custom synthesis a wide range of analytical services are offered to industry. The successful applicant will be expected to collaborate closely with industrial sponsors and ideally will be aged between 21 and 25 with a degree (or equivalent) in Chemistry. An interest in Biology would be helpful, although not essential. Part-time registration for a higher degree will be considered. The salary will be on a scale £3,775 to £4,333.

Applications including two referees should be sent as soon as possible to Professor R. Baker, Department of Chemistry, The University, Highfield, Southampton SO9 5NH. Please quote Ref. N. 2158(A)

## THE WORLD HEALTH ORGANISATION

invites applications for a post of Medical Officer (Chief of Cancer Unit) in the Division of Noncommunicable Diseases, W.H.O. Headquarters, Geneva.

The incumbent of the post will be responsible for the planning, organisation and evaluation of the programme in the field of cancer control and prevention at headquarters level, and its coordination with regional office and the International Agency for Research on Cancer.

Applicants should have a medical degree, with specialisation in an area of oncology. Experience in organising and evaluating cancer control programmes, and clinical experience are essential; statistical and research experience, as well as experience in international health work, are desirable. Excellent knowledge of English or French, with working knowledge of the other language is required.

Interested candidates with the required qualifications should write as soon as possible, enclosing a detailed curriculum vitae and quoting reference VN/CAN, to:

**The World Health Organisation  
Personnel  
CH-1211 Geneva 27**

Only candidates under serious consideration will be contacted.

W171(A)

## UNIVERSITY OF LIVERPOOL DEPARTMENT OF MICROBIOLOGY

Applications are invited for the post of a postdoctoral Research Fellow in the Department of Microbiology.

The research which is under the direction of Professor H. R. Perkins, will be concerned with the structure and biosynthesis of the bacterial envelope in relation to antibiotic action.

The post is financed by the M.R.C. and the initial salary will be within the range £4,232 to £5,591 per annum.

Applications, together with the names of two referees, should be received not later than July 13, 1979 by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/647/N. 2143(A)

## UNIVERSITY OF PENNSYLVANIA POSTDOCTORAL POSITION to study control of Gene Expression and Steroid Hormone/Chromatin Interactions in Cultured Human and Murine Mammary Tumour Cells

Applicant must have strong biochemistry background. Experience with fractionation techniques, nucleic acid hybridization, steroid hormones, antibody production, and/or tissue culture desirable. Send resume, three letters of recommendation and university record to Dr Fred R. Frankel, 249 Johnson Pavilion, University of Pennsylvania, Phila. Pa. U.S.A. 19104. W168(A)

## ANTWERP UNIVERSITY Belgium

CARDIOVASCULAR INSTITUTE  
Applications are invited for a post  
RESEARCH ASSISTANT

tenable for 1 year (starting 01.07 to investigate the ionic activities heart cells.

Salary range: 557.768 BF to 809. BF.

Candidates should have a good degree in biophysics, physiology, medicine or other related sciences with particular interest in electrical properties of excitable membranes.

Applications giving details of cation, experience and names addresses of two referees should be sent by June 20, 1979 to Personnel Department, Universitaire Instelling Antwerpen, Universiteitsplein 1, Wilrijk, Belgium.

Further details can be obtained from Prof. dr. D. L. Brutsaert, Groenenkerkeaan 171, 2020 Antwerpen, 031/30.59.80. W162(A)

## BIOCHEMIST, CHEMIST & IMMUNOLOGIST

available summer 1979 Kiel/Germ to continue in a project on reproductive immunology working with gen analysis and tissue cultures reported by the German Research Foundation. Post doctoral status preferred not absolutely necessary. Send curriculum vitae, credentials and reference to: Dr. Mettler, Laboratory of Human Reproduction, Dept. Obst. and Gyn. University of Kiel, 2300 Kiel, Holtenauerstr. 4, W. Germany. W164(A)

# **SHEFFIELD SOUTHERN HEALTH DISTRICT (TEACHING)**

DEPARTMENT OF BACTERIOLOGY

## **NON-MEDICAL BACTERIOLOGIST**

(Basic Grade or Probationer)

required to work in the Group Department of Bacteriology situated at the Hallamshire Hospital and The Jessop Hospital for Women.

Applicants should possess a 1st or 2nd class Honours Degree in Biological Sciences and should have spent part, preferably the major part, of their course in Microbiology.

Whitley Council Conditions of Service apply.

Salary Scale £3,486 to £4,275 per annum for new entrants to the Health Service. Visits welcomed, by appointment with Mr J. M. Hindmarch, Principal Non-Medical Bacteriologist, Hallamshire Hospital (Telephone 0742-26484, Ext. 2607).

Applications stating age, qualifications and experience and naming two referees to the:

District Personnel Officer, District Personnel Office, B Floor, Hallamshire Hospital, Glossop Road, Sheffield S10 2JF.

Closing date for application: June 25, 1979.

2123(A)

# **UNIVERSITY OF READING**

## **LECTURESHIP**

at

## **THE NATIONAL COLLEGE OF FOOD TECHNOLOGY**

(SECOND ADVERTISEMENT)

Applications are invited for a Lectureship, tenable at the National College of Food Technology, Weybridge, from persons with qualifications and experience in applied microbiology preferably of particular relevance to the food industry. The successful candidate will be expected to contribute to teaching at undergraduate and post-graduate levels and develop an experimental research programme. Opportunities for research are available in all aspects of food microbiology.

The appointment will be made from a date to be arranged with the successful candidate.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH by whom applications should be received not later than August 31, 1979.

Applicants for the post advertised in March/April need not reapply.

2107(A)

# **QUEEN ELIZABETH COLLEGE Kensington**

(University of London)

## **POSTDOCTORAL RESEARCH ASSISTANT PHYSICS DEPARTMENT**

Applications are invited for a postdoctoral Research Assistant to work on the development of a set of computer programmes which will produce in real time the neutron diffraction data collected by the D 9 actometer multidetector at Institut e-Langevin, Grenoble. Applicants should ideally have some experience in crystallography and in high and level language computer programming. The work will be carried out mainly at Q.E.C., but will involve regular visits to I.L.L.

The appointment will be for one year from September 1, 1979 in the instance, with the possibility of extension. Initial salary in the range £12 to £15,048 per annum (under 30) plus £502 per annum London allowance.

Applications to Dr C. Wilkinson, Physics Department, Queen Elizabeth College, Campden Hill Road, London W8 7AH from whom application forms are obtainable.

2131(A)

# **UNIVERSITY OF LIVERPOOL DEPARTMENT OF BIOCHEMISTRY**

Applications are invited from biochemists for the postdoctoral post of

## **SENIOR RESEARCH ASSISTANT**

to work on the biochemistry of fluorescent iron-binding chromophores synthesized by some bacteria. A role in iron metabolism has only recently been ascribed to some of these pigments. Familiarity with the concepts and techniques of microbiology would be advantageous. The project is financed for a period of three years.

Initial salary in the range £4,232 to £4,776 per annum with U.S.S. benefits.

Applications, together with the names of two referees, should be received not later than July 5, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/644/N.

# **EUROPEAN SCIENCE FOUNDATION**

## **EUROPEAN TRAINING PROGRAMME**

in

## **BRAIN AND BEHAVIOUR RESEARCH**

### **TRAINEESHIPS**

Traineeships of three, six or rarely nine months are offered to promising young scientists working in the area of brain and behaviour research in order to broaden their skills and knowledge in a field other than but related to their own. The grants are given to allow them to learn a particular technique abroad for which training is not offered in their own country. The trainee is expected to return to her/his original post upon termination of her/his training so that her/his institute will in turn be able to benefit from newly acquired skills.

All applications have to be accompanied by a letter of recommendation by the sending institute and by a letter of acceptance from the receiving institute. Preference is given to post-docs under the age of 35.

### **TRAVEL GRANTS**

Travel grants are awarded to allow young research workers to visit another laboratory in connection with an on-going research project or to participate in international meetings and symposia. In addition special grants are to be awarded to students to enable them to take part in the yearly meetings of the European Neuroscience Association (ENA) which this year will take place in Rome on September 10-14.

Applications should be accompanied by letters of recommendation from the sending institute and of invitation from the institute to be visited. Applicants should be postgraduate research workers with the exception of applications to attend the yearly ENA meeting. In this particular case preference is given to postgraduate students.

The deadline for completed applications is March 15 and September 15. Further information and application forms may be obtained from:

# **UNIVERSITY OF OXFORD NUFFIELD PROFESSORSHIP OF ANAESTHETICS**

Electors intend to proceed to an election for the Nuffield Professorship of Anaesthetics which falls vacant on July 1, 1980. The stipend of the professor will be £12,084 per annum. Applications (twelve copies), naming referees but without testimonials, should be received not later than July 27, 1979 by the Registrar, University Offices, Wellington Square, Oxford OX1 2JD, from whom further particulars may be obtained.

2080(A)

Public Health Laboratory Service Board  
61 Colindale Avenue, London NW9 5EQ

## Curator

(Consultant Medical Microbiologist  
OR Top grade Microbiologist)  
**National Collection of Type Cultures**  
**Central Public Health Laboratory**  
**Colindale**

Applications are invited from medical and non-medical graduates for the whole-time post of Curator of the National Collection of Type Cultures. The primary function of the NCTC is to hold and supply authenticated bacterial cultures for education, control, assay, taxonomic and other purposes to PHLS Laboratories, Universities, Medical Schools, Hospitals and Industry. Other functions include the provision of an identification service for bacteria of medical relevance that are difficult to classify, research on bacterial taxonomy (classification, nomenclature, identification), and the provision of freeze-drying facilities for other PHLS Laboratories. A higher qualification is essential.

The Laboratory may be visited by arrangement with the Acting Curator, Dr L. R. Hill, National Collection of Type Cultures, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Telephone: 01-205 7041.

Salary on NHS Consultant or Top grade Scientific Officer scale; other terms and conditions of service generally as for appointments in the NHS.

Full particulars may be obtained from the Secretary to the PHLS Board, to whom applications should be sent to arrive not later than July 6, 1979, stating date of birth, qualifications, experience and published work, and naming three referees.

2077(A)

University of London

**FLUID MECHANICS ON  
THE DISTRIBUTED  
ARRAY PROCESSOR**

S.R.C. is funding research here into the Large Eddy Simulation of Turbulence and has awarded a grant for application of the Distributed Array Processor to this work. The D.A.P., a fundamental development in computer architecture, is particularly suited to solving the Navier-Stokes equations for fluid motion. Applications are invited from those with relevant experience of large programmes (D.A.P. uses a variant of FORTRAN); preference will be given to those with a knowledge of fluid mechanics.

Appointment for 27 months in first instance with initial salary up to £7,388 per annum (including London Allowance), review in October 1979.

Further details available from Professor D. C. Leslie, Nuclear Engineering Department, while applications with curriculum vitae, publications and names of two referees, should be sent to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS. 2135(A)

**MANCHESTER  
POLYTECHNIC  
DEPARTMENT OF  
CHEMISTRY  
LECTURER II  
IN CHEMISTRY**

Applicants should be broadly experienced in the practice of Analytical Chemistry, and a special interest in the analytical aspects of organic chemistry would be particularly appropriate. Applicants should have a keen interest in contributing to the development of research activity in appropriate fields, and teaching and/or industrial experience would also be an advantage.

The successful applicant will contribute to the teaching of Chemistry (particularly Analytical) on H.N.C./H.C., H.N.D./H.D., Grad. R.I.C., B.Sc. and M.Sc. courses in Chemistry, and also to the service teaching of Chemistry to students on courses in Biological Sciences, Polymer Science and Technology, Food Technology, Science Education etc.

Salary scale: £4,101 to £6,558. For further particulars and application form (returnable by June 30, 1979), please send a self-addressed envelope marked "T/491" to the Secretary, Manchester Polytechnic, All Saints, Manchester M15 6BH. 2079(A)

**Join  
the Nuclear  
Research  
Team**

### RESEARCH OFFICER

**OPPORTUNITY FOR CANADIAN CITIZENS  
LIVING ABROAD**

The Materials Science Branch of the Chemistry and Materials Division at Chalk River Nuclear Laboratories is looking for a scientist to join an active group seeking a fundamental understanding of the effect of irradiation on the creep and growth of zirconium alloys in nuclear reactors. The work will include the formation and migration of point defects in very high purity zirconium and their interaction with trace impurities. The successful candidate will also be expected to perform basic research in the field of irradiation effects and to examine the effect on mechanical properties of zirconium alloys.

Candidates should have a Ph.D. degree in physical metallurgy, solid state Physics or related areas of science. In addition, applicants who have an advanced degree with relevant experience will also receive full consideration. Experience with radiation effects studies, tracer diffusion, and techniques for preparing high purity transition metals would be an advantage.

Salary dependent on qualifications and experience. We offer good benefits package and a removal allowance to assist with moving expenses.

Chalk River Nuclear Laboratories is located 190 kilometres north-west of Ottawa on the Ottawa River. Excellent educational facilities and year-round cultural and recreational activities are available in the Deep River-Pembroke area.

Qualified men and women are invited to apply in confidence quoting file 5A to Employment Supervisor, Atomic Energy of Canada Limited, Research Company, Chalk River Nuclear Laboratories, Chalk River, Ontario K0J 1J0. W161(A)

**Atomic Energy  
of Canada Limited**

**L'Énergie Atomique

CENTRAL DISTRICT**

### RESEARCH TECHNICIAN

For the University of Gastroenterology Research Laboratory, Manchester Royal Infirmary, which is undertaking investigations into Coeliac disease. The work involves tissue culture of the small intestine. Previous experience in biochemical techniques advantageous.

The appointment is for two years in the first instance. Salary will be in the range of £2,991 to £4,899 per annum depending on qualification and experience.

Informal enquiries to Mr R. Lobley. Tel. 061-273 3300, Ext. 179.

Application form and job description from the Deputy Administrator, Manchester Royal Infirmary, Oxford Road, Manchester M13 9WL. Closing date July 2. 2139(A)

**WELSH NATIONAL  
SCHOOL OF MEDICINE  
(University of Wales)  
DEPARTMENT OF  
MEDICAL BIOCHEMISTRY  
RESEARCH OFFICER**

required in the above Department at Heath Park, Cardiff to work on the development and application of assays of human corticotrophin using labelled antibodies. The project is funded for a period of three years and would be suitable for a biochemistry graduate wishing to read for a higher degree. Salary will be £3,689 per annum.

Further particulars and application forms quoting Ref. No. C38/4/28 may be obtained from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN. 2145(A)

**ST GEORGE'S HOSPITAL  
MEDICAL SCHOOL  
(University of London)  
RESEARCH ASSISTANT  
IN BIOCHEMISTRY**

Applications are invited from recent or 1979 honours graduates in biochemistry or chemistry to study mechanisms of biosynthesis, intracellular transport and proteolysis of secreted polypeptides. The appointment is for three years and is expected to lead to a Ph.D. degree. Minimum emoluments from October 1, 1979 £4,277 per annum.

Applications including a curriculum vitae and names and addresses of referees, should be sent immediately to Dr B. M. Austen, Department of Peptide Chemistry, National Institute for Medical Research, Mill Hill, London NW7 1AA. 2134(A)

# newscientist Editor

Dr. Bernard Dixon will be leaving New Scientist this Autumn to pursue other science writing interests. Applications are invited for the post of Editor. New Scientist is the world's leading science news weekly, occupying a unique position between professional journals and news magazines. It appeals to readers with widely diverse interests—students, professional scientists, businessmen and those with a general interest in science and technology. The circulation of the magazine has been growing steadily during the 70's to its current level of over 80,000 copies a week.

Applicants who have not held senior positions in science journalism are unlikely to have the experience required.

Applications will be treated in the strictest confidence and should be made in writing with comprehensive career details to Michael Godfrey, Publisher, New Scientist, IPC Magazines Limited, 2625 King's Reach Tower, Stamford Street, London SE1 9LS.

2138(A)

## UNIVERSITY OF DURHAM

DEPARTMENT OF  
CHEMISTRY

### RESEARCH TECHNICIAN GRADE 5

Applications are invited from suitably qualified persons for an R.C. funded post of a Research Technician (Grade 5) in the S.C.A. group. The post arises from a new S.R.C. funded grant proposal on Structure, Bonding and Reactivity of Polymer Surfaces and will be to February 1981 in the first instance from August 1, 1979 or a mutually agreeable date soon after.

The person appointed will be expected to make routine measurements of high energy (E.S.C.A.) photoelectron Spectrometers, prepare samples and organise spare equipment in the E.S.C.A. laboratories under the direction of Professor D. T. Clark. Initial salary £3,474 per annum.

Application forms and further details from:

Personnel Officer,  
University Office,  
Old Shire Hall,  
Durham DH1 3HP

whom completed forms should be returned by June 29, 1979.

2141(A)

## CHELSEA COLLEGE University of London UNIVERSITY OF GHANA TEMPORARY LECTURESHIP IN GEOPHYSICS

An Inter-University Council supported link scheme has existed since 1976 between the Geology Departments of Chelsea College and University of Ghana. The scheme includes the post of Lecturer in Geophysics under the Home Base Scheme and applications for this post are invited.

The appointment is as Lecturer in the Geology Department, Chelsea College, for a period of two and a half years but the first two will be spent on secondment to the University of Ghana. Duties there will include undergraduate teaching of pure and applied geophysics and research in seismology, including the operation of a seismograph station that has been recording since 1976, and aspects of applied geophysics.

Salary scale while at the home base is £4,232 to £8,452 per annum plus £502 London Allowance.

At the University of Ghana the salary scale Cedis 6,420 to Cedis 9,780 (£1=Cedis 5.50 approx.) would be supplemented under the British Expatriate Supplementation Scheme where appropriate. This scheme provides salary supplementation in the range £6,018 to £7,068 married and £3,504 to £4,296 single (under review), plus appointment grant, allowances for family passages, education allowance and children's holiday visit passages, etc.

Further details and application forms from the Personnel Officer, Chelsea College, Friese Greene House, Chelsea Manor Street, London SW3 3TW. Applications to be received by July 3, 1979.

2084(A)

# CSIRO AUSTRALIA Division of Radiophysics Appointment of Group Leader in Solar Radio Astronomy Group Sydney NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

**General:** The Solar Radio Astronomy Group has a total staff of 36, including 10 research scientists. Solar observations are carried out at the CSIRO Solar Radio Observatory at Culgoora near Narrabri, NSW, where 16 of the staff are resident. The principal observing instruments are the 3-frequency radioheliograph (now being converted to 4-frequency operation), the 8-8,000 MHz radio spectrograph the 24-220 MHz spectro-polarimeter (now being extended to 660 MHz) and a high-sensitivity acousto-optic spectrograph.

Interpretation of the observational data and the development of observing instruments are conducted at the Divisional Headquarters at Epping a Sydney suburb.

A major instrumental development now in progress is the conversion of the radioheliograph to a synthesis telescope using digital correlator techniques. Solar research topics include: emission mechanisms of solar radio bursts; the structure of the corona; characteristics of shock waves and particle emissions associated with radio bursts. The Group conducts collaborative studies with other national and international institutes and will be actively participating in the coming Solar Maximum Mission and other Space Laboratory missions.

**Duties:** The appointee will be responsible for the direction of the research activities of the Solar Group and will be expected to plan areas of research into solar radiophysics and maintain close contact with national and international groups engaged in similar fields.

**Qualifications:** PhD or equivalent qualifications with a background in physical science or engineering and a record of personal achievements in research and leadership.

**Tenure:** Appointment to the Organization is for an indefinite period with superannuation. The position of Solar Group Leader will be for a negotiable term of about five years, with options for further terms if mutually desired, or to a senior position in the Group.

**Salary:** Senior Principal Research Scientist A\$27,790—A\$30,530 p.a.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 780/621 should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 30th August, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

2148(A)

## CENTRAL PUBLIC HEALTH LABORATORY MEDICAL LABORATORY SCIENTIFIC OFFICER

A.I.M.L.S. or H.N.C.  
in Microbiology

required in the Division of Microbiological Reagents and Quality Control to assist in the production development and quality control of diagnostic reagents.

Applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Telephone: 01-205 7041.

2075(A)

## UNIVERSITY OF DURHAM DEPARTMENT OF CHEMISTRY

Applications are invited for the post of Senior Demonstrator in Inorganic/Physical Chemistry for one year, from October 1, 1979.

Initial salary in the range £3,775 to £5,199 per annum, on scale 1A or 1B (depending upon qualifications) plus U.S.S.

Applications (three copies) naming three referees should be sent by June 30, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

2118(A)

## CSIRO AUSTRALIA

### Division of Materials Science Parkville, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

**Field:** Catalysis.

**General:** The Division is engaged in a broad area of Surface Science, Materials Research and Production Technology. It operates laboratories at Parkville, Fitzroy and Fishermen's Bend in Victoria and at Woodville in South Australia. The appointees will be located at the Catalysis and Surface Science Laboratory, University of Melbourne, Parkville, Victoria.

**Position No. 1. Ref. No: 370/348**

## Postdoctoral Research Fellow

**Duties:** To participate in a research group studying catalytic processes for fuel synthesis and processing; particularly reactions of cyclic hydrocarbons and heterocyclics in order to develop new catalysts for hydrotreating of petroleum and coal products.

**Tenure:** The Fellowship will be for a period of five years. Superannuation is available.

**Position No. 2. Ref. No: 370/347**

## Research Scientist

**Duties:** To participate in a research group studying catalytic processes for fuel synthesis and processing; in particular to investigate the preparation, characterization and use of dispersed metallic catalysts for hydrocarbon conversions and related processes.

**Tenure:** Indefinite with superannuation.

**Salary:** (for both positions) Research Scientist A\$15,422—

A\$18,904 pa or Senior Research Scientist A\$19,572—A\$22,405 pa.

**Qualifications:** (for both positions) A PhD degree in Chemistry or Chemical Engineering or equivalent.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the appropriate reference number(s) should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by 13th July, 1979. Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue N.W., Washington D.C. 20036.

2147(A)

Dundee College of Technology Department of Molecular & Life Sciences

## SENIOR LECTURESHIP/ LECTURESHIP IN BIOLOGICAL SCIENCE

Applicants should have an honours degree and a higher degree in biochemistry, mammalian physiology, or microbiology and extensive research or industrial experience. The person appointed will be required to make a substantial contribution to the teaching of biological sciences in degree, HND and HNC courses; he/she will also be expected to make a major contribution to course development, research, staff development and departmental administration.

## LECTURESHIPS IN CHEMISTRY (TWO POSTS)

Applicants should have an honours degree and a higher degree in chemistry and suitable industrial or research experience. The persons appointed will be expected to make a contribution to the teaching of chemistry in degree, HND and HNC courses; they will also be expected to contribute to course development, research and departmental administration.

**Salary Scales:** (presently under review) Senior Lectureship—£7,155—£7,962 (bar)—£9,042; Lectureship—£4,056—£7,167 (bar)—£7,698.

Initial placing on these scales will depend upon approved prior experience. Further particulars and application forms obtainable from the Administrative Assistant (Establishment), Dundee College of Technology, Bell Street, Dundee, DD1 1HG, to whom completed application forms should be returned by 29th June, 1979.

2103 (A)

## UNIVERSITY OF DURHAM DEPARTMENT OF CHEMISTRY

Applications are invited for the post of Temporary Lecturer in Organic Chemistry for three years from October 1, 1979. It is hoped that applicants will already have some lecturing experience. An interest in some branch of organofluorine chemistry or polymer chemistry (preparative or structure and bonding by means of photoelectron spectroscopy) and a willingness to join existing groups working in these fields would be an advantage.

Initial salary on the range £4,333 to £8,992 per annum, with superannuation.

Applications (three copies) naming three referees should be sent by June 30, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

2120(A)

## SOUTHAMPTON UNIVERSITY WOLFSON CENTRE FOR ELECTROCHEMICAL SCIENCE RESEARCH SCIENTIST

Applications are invited for the position of Research Scientist in the Wolfson Centre for Electrochemical Science, which is a contract research organisation offering a service to industry in all fields of pure and applied electrochemistry and electrochemical engineering.

Applicants should have a Ph.D. in a relevant subject or equivalent industrial experience. The salary will be within a range from £4,000 to £6,000 per annum (under review). Superannuation benefits, assistance towards relocation expenses.

Applicants should send a curriculum vitae together with the names of two referees to Mr D. A. S. Copland, The University, Southampton SO9 5NH, quoting reference 203/R.

2117(A)

## UNIVERSITY OF BRISTOL DEPARTMENT OF BOTANY RESEARCH ASSISTANT to work on

### Root Surface Microorganisms

A N.E.R.C. funded research assistant post is available for 3 years starting September 1979, to investigate the influence of environmental factors on the abundance of root-surface microorganisms and on exudation by roots. Starting salary £3,689 per annum (scale subject to revision on October 1st, 1979). Opportunity to work for a higher degree. Qualifications required: good honours degree in biology, microbiology or a related subject. Further particulars from, and applications to, Dr E. I. Newman, Botany Department, The University, Bristol BS8 1UG. Closing date for applications July 9, 1979.

2098(A)

Applications are invited for the position of

### ASSISTANT PROFESSOR

(Tenure Track) of engineering science. Positions are available in September 1979 and January 1980. Applicants should possess a Ph.D. in engineering or a related physical science and have demonstrated the ability to generate original research. The positions involve research, teaching graduate and undergraduate courses and the guiding of graduate student research. Applicants should submit a curriculum vitae, the names and addresses of three referees and a statement of teaching and research interests to A. M. Strauss, Head, Department of Engineering Science, M.L. #112, University of Cincinnati, Cinn. OH 45221. The University is an Equal Opportunity Affirmative Action Employer.

W166(A)

## UNIVERSITY OF WARWICK RESEARCH FELLOW IN PHYSICS/PHYSICAL CHEMISTRY

(Collaborative appointment with the University of Cambridge)

Applications are invited for the above post to work in a joint project with Professor J. M. Thomas (Cambridge) and Dr R. F. Pettifer (Warwick) in a study of the characterisation of catalysts by extended X-ray absorption fine structure (EXAFS).

The successful applicant will be based at Warwick University, but will travel frequently to both Cambridge and the Daresbury Laboratory to work with the new synchrotron radiation source.

Applicants should possess a post-graduate degree in either physics or surface chemistry. A knowledge of EXAFS or catalysts would be an advantage, but not essential. The post is offered for three years starting between October 1, 1979 and February 1, 1980 on the research range 1A scale, £4,232 to £7,145 per annum.

Further particulars and application forms available from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting ref. No 44/2A/79, to whom completed applications should be returned as soon as possible.

2122(A)

## HERPETOLOGIST HARVARD UNIVERSITY

Harvard University seeks to make a tenure-track appointment in herpetology of an assistant or associate professor in the Department of Biology, who will serve conjointly as an assistant or associate curator in The Museum of Comparative Zoology. Preference will be given to candidates with (1) a strong research program in herpetology, (2) ability to offer instruction at the undergraduate and graduate levels, and (3) commitment to supervise and enhance a major herpetological collection. The closing date for receipt of applications is October 15, 1979, and the appointment will take effect July 1, 1980. Applicants should send a curriculum vitae, statement of research interests, and names of three references to: Herpetology Search Committee, Office of the Chairman, Department of Biology, Harvard University, Cambridge, Massachusetts 02138. Harvard is an Equal Opportunity/Affirmative Action Employer.

W160(A)

## THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN MEDICAL BIOPHYSICS

Applications are invited from engineers or physical scientists who wish to join a small interdisciplinary group working on the important problem of incontinence. The appointee would be expected to take a particular interest in models of the bladder and urethra and to apply this work to the design of artificial drainage systems for the management of incontinence. The appointment is for up to three years. Starting salary range per annum: £4,232 to £5,300 (£4,833 to £5,488 from October 1979). Further information from Professor B. R. Pullan, Department of Medical Biophysics, Stopford Building, The University, Oxford Road, Manchester M13 9PT.

# Palynologist

We are looking for a Palynologist to apply palynology to the biostratigraphical discrimination, dating and correlation of samples from geological surveys and exploration wells as part of our central service to exploration areas world-wide.

The salary will be determined according to age and experience. Fringe benefits include a non-contributory pension scheme, 4 weeks' annual leave, relocation expenses and excellent sports and social facilities.

If you have a good honours degree in Geology plus at least one year's post-graduate training/experience in palynology and are interested in a career with BP, then please write giving details of your career, qualifications and experience to:

Mrs. L. Fuller,  
Personnel & Administration,  
BP Research Centre,  
Chertsey Road,  
Sunbury-on-Thames,  
Middlesex TW16 7LN.

**BP Research Centre**  
**Sunbury on Thames**

2164(A)

## Agricultural Research Council INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

# BIOMETRICIAN

An experienced BIOMETRICIAN is required in the Statistics Section of the Institute. The successful applicant will be required to specialise in microbiological problems in infectious disease and to identify areas of research which would benefit from greater statistical involvement. The work will also require collaboration with research scientists and supervision of junior statisticians in the Section which has a remote computer link to the ICL 4/70-72 at Rothamsted Experimental Station.

Candidates should have a Degree, HNC or equivalent in Mathematics/Statistics and will normally be expected to have had at least five years' relevant practical post qualifying experience. Salary in a scale (£4,101 to £5,448), currently under review.

The ARC Pension Scheme is non-contributory.

The Institute is set in pleasant surroundings in a rural area with a staff restaurant and good recreational facilities. Accommodation for a single person can be provided if required.

Application Forms from: Secretary, Institute for Research on Animal Diseases, Compton, Newbury, Berkshire quoting reference number 409.

2133(A)

## STUDENTSHIPS

### PORTSMOUTH POLYTECHNIC DEPARTMENT OF BIOLOGICAL SCIENCES

#### S.R.C. C.A.S.E. Studentships

**Post 1 Title:** The use of tree-rings as a means of dating timbers from historical sites.

Supervisor: Dr F. A. Hibbert.

Co-operating body: Department of Environment, Ancient Monuments Laboratory, London.

**Post 2 Title:** Microbial infestation of Diesel fuel storage delivery systems.

Supervisors: Drs R. A. Eaton and E. B. G. Jones.

Co-operating body: Ministry of Defence, Central Dockyard Laboratory, Portsmouth.

#### S.R.C. Studentship

**Post 3 Title:** Oogenesis in developmentally retarded tadpoles of *Xenopus laevis*.

Supervisor: Dr T. A. J. Reader.

#### S.R.C. Advanced Course Studentships

### M.Sc. COURSE IN THE BIODETERIORATION OF MATERIALS

A number of S.R.C. awards are available for suitably qualified students who wish to apply for the above course.

Starting date for all posts: October 1, 1979.

Applications to include a curriculum vitae and the names of two referees should be sent to the Administrative Assistant, Department of Biological Sciences, Portsmouth Polytechnic, King Henry 1 Street, Portsmouth PO1 2DY from whom further information can be obtained if desired.

Closing date for all applications: June 28, 1979. 2071(F)

### UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL S.R.C. C.A.S.E. STUDENTSHIPS

Three S.R.C. C.A.S.E. awards will be available in the Department of Physiology and Pharmacology in collaboration with I.C.I. (2) and Reckitt and Colman from October 1, 1979. They are for research (leading to a Ph.D.) in the following areas:

1. A physiological and pharmacological study of some of the factors contributing to the development of hypertension using rats with arterial hypertension induced by short-term isolation. Supervisor Dr T. Bennett.
2. Two projects on CNS neurotransmitters and their possible role in mental disease. (a) Effects of 5-hydroxytryptamine (5HT) agonists and antagonists on brain 5HT metabolism and release. Supervisor Dr C. A. Marsden. (b) Interactions between CNS thyrotropin-releasing hormone and biogenic amine release. Supervisors Drs G. W. Bennett and C. A. Marsden.

Applicants, honours graduates or prospective honours graduates in physiology, pharmacology or related biological subjects, should write, as soon as possible, giving a brief curriculum vitae and the names and addresses of two referees, to Professor P. H. Fentem, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH.

For further details about the projects please contact the relevant supervisors: Tel. 0602 700111, ext. 3297 (GWB/CAM) or 3600 (TB). 2092(F)

### U.M.I.S.T. POSTGRADUATE STUDIES IN CORROSION SCIENCE CORROSION AND PROTECTION CENTRE

Applications are invited from candidates possessing or expecting a good degree in science or engineering, or a suitable professional qualification, who wish to undertake postgraduate studies in corrosion science and engineering. The U.M.I.S.T. Corrosion and Protection Centre involves over 100 academic, technical and postgraduate staff and students, and is well equipped with a variety of modern electronoptical and electrochemical techniques.

There are S.R.C./C.A.S.E. studentships or equivalent financial support available for research in a number of areas of corrosion and protection, including:

- (1) Electrochemical studies of paints.
- (2) Electrolytic colouring of aluminium.
- (3) Microbial corrosion.
- (4) High temperature corrosion in low oxygen gases.
- (5) Breakdown of oxide scales by sulphur.
- (6) Glasses as anti-corrosive agents.
- (7) Oxidation of steels in Co/Co<sub>2</sub>.
- (8) Oxidation of ion implanted alloys.
- (9) Aluminium anodes for cathodic protection.
- (10) Mechanisms of inhibition of aluminium by paints.
- (11) Corrosion of ion-implanted magnesium.

Research students are expected to register for the degree of M.Sc. (by research) or Ph.D.

Applications will also be considered for the postgraduate courses in Corrosion Science or Terotechnology offered by the Centre.

All applications and enquiries should be addressed to Professor G. C. Wood, Corrosion and Protection Centre, University of Manchester Institute of Science and Technology, P.O. Box 88, Manchester. 2126(F)

### ROYAL HOLLOWAY COLLEGE (University of London) S.R.C. STUDENTSHIP DEPARTMENT OF BIOCHEMISTRY

Applicants should have, or expect to gain this year, a good honours degree in Biochemistry for this research studentship tenable for 3 years and leading for a Ph.D. degree. The project, under the direction of Dr C. Rider, is an investigation of multiple molecular forms of mammalian enzymes of citrate metabolism and a variety of techniques in enzymology will be employed.

Applications together with names and addresses of two referees should be sent to the Registrar, (N) Royal Holloway College, Egham Hill, Egham, Surrey. 2086(F)

### UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS C.A.S.E. STUDENTSHIP

for work on readout noise sources (involving slice level testing), in SILICON DIODE ARRAYS in collaboration with I.P.L. Dorchester. The main interest is in low light level imaging for astronomy.

Applications should be sent to Dr J. M. Breare, Department of Physics, Science Laboratories, South Road, Durham DH1 3LE (Tel: 0385 64971), from whom further particulars may be obtained. 2091(F)

UNIVERSITY OF  
LIVERPOOL  
DEPARTMENT OF  
METALLURGY AND  
MATERIALS SCIENCE  
S.R.C. C.A.S.E.

AND A.E.R.E. HARWELL

sponsored Research Studentships

Applications are invited from good honours (1st or 2(1)) graduates in Metallurgy / Materials Science or related Physical Sciences for three year sponsored research studentships tenable from October 1, 1979. The research projects are in the following areas:

- (a) Structure and Embrittlement of Low Alloy Ferritic Steels (two positions).

Research into the relation between micro-structure, segregation of alloy and impurity elements to grain boundaries and susceptibility to intergranular fracture in ferritic steels used for power engineering structures in collaboration with A.E.R.E. Harwell. Supervisors: Prof. B. L. Eyre and Dr B. C. Edwards.

- (b) Stress Corrosion Cracking in Aluminium Alloys.

Research into the relation between the atomic structure of grain boundaries and observed rates of intergranular stress corrosion in commercial aluminium alloys in collaboration with Alcan Industries. Supervisors: Dr R. C. Pond and Dr C. Tuck.

- (c) Light-Ion Bombardment of Non-metallic Materials.

To investigate the effects of light, gas ion bombardment on the micro-structure and surface of ceramic materials having potential for use in fusion reactors in collaboration with the Culham Laboratory. Supervisors: Dr D. J. Bacon and Dr K. Ereus.

- (d) Studentships and projects are also available in other areas, viz. heat treatment of steels, computer simulation of crystal defects, development of composite materials, mechanical properties of metals, properties of cellular materials and the properties of bio-materials.

Applications should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/630/N. 2105(F)

UNIVERSITY OF  
LIVERPOOL

DEPARTMENTS OF BOTANY  
AND INDUSTRIAL STUDIES

Applications are invited for a S.R.C./S.S.R.C. Research Studentship tenable from October 1979 to study the importance of zinc and copper chelation in the tolerance of plants to these metals and the occurrence of chelates in polluted environments. The project will be jointly supervised by the Departments of Botany and Industrial Studies.

Applicants must possess or expect to gain a good honours degree in chemistry or a biological science. Applications, including details of academic experience and the names of two referees, should be received not later than July 2, 1979, by The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/641/N. 2127(F)

N.E.R.C. RESEARCH  
STUDENTSHIP

Applications are invited for a Ph.D. studentship in Fish Physiology. The title of the project is "The effects of exercise, diet and pollutants on protein metabolism in fish." The successful applicant would be expected to possess a 1st or a 2 (1) Honours degree or the equivalent in Zoology, Biology, Physiology or Biochemistry. Applications, which should include the names of two referees, should reach Professor G. Goldspink, Department of Zoology, University of Hull, not later than July 7, 1979. 2140(F)

UNIVERSITY OF  
LIVERPOOL  
DEPARTMENT OF  
MICROBIOLOGY

RESEARCH STUDENTSHIPS

1. S.R.C. (C.A.S.E.) Award to Dr G. O. Humphreys in association with Dr P. Barth, Corporate Laboratories, I.C.I. Ltd., entitled "Heterospecific expression problems in DNA cloning" to study the barriers to heterospecific expression by using hybrid plasmids. It is proposed to seek plasmids occurring naturally in *Arthrobacter* and to prepare hybrid replicons between these and others from *E. coli*.

2. S.R.C. Studentship. The project, to be undertaken with Dr C. Edwards, is entitled "Bioenergetics of the microbial cell cycle". Synchronous cultures of *Azotobacter vinelandii* grown under different conditions will be used to examine the periodic changes in respiratory events such as  $QO_2$  effects of inhibitors and ATPase levels.

3. M.R.C. Studentship. The project, to be undertaken with Professor H. R. Perkins, is entitled "Peptidoglycan synthesis by *Neisseria gonorrhoeae*". The type of peptidoglycan synthesized in an *in vitro* system will be studied in relation to the action of various  $\beta$ -lactam antibiotics, which have different effects.

All studentships commence October 1, 1979. Applicants should hold or expect to obtain at least an upper second class Honours degree in Microbiology, Biochemistry or other relevant discipline.

Applications, together with details of academic experience and the names of two referees, should be received not later than July 13, 1979, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref. RV/646/N. 2144(F)

UNIVERSITY OF SURREY  
DEPARTMENT OF  
BIOCHEMISTRY  
S.R.C. C.A.S.E.

RESEARCH STUDENTSHIPS

Research studentships, for work on the topics listed below, are available in the Department of Biochemistry. The studentships, which are financed by the Science Research Council in collaboration with industry and other organisations, commence on October 1, 1979 and are tenable for three years.

1. Inter-species variations in microsomal oxygenation reactions, in collaboration with The Flour Milling and Baking Research Association, Chorleywood.
2. The nutritional effects of different varieties of bran, in collaboration with The Flour Milling and Baking Research Association, Chorleywood.
3. Effects of the lysosomal stabiliser, carbenoxolone, on carcinogenesis, in collaboration with Biorex Laboratories Limited, London.
4. Stereospecific drug modification using Cytochrome P-450, in collaboration with May and Baker Limited, Dagenham.
5. Development of an inhibitor-based EIA for drug analysis in serum, in collaboration with The Royal Sussex Hospital, Brighton.
6. Metabolism and excretion of monosubstituted imidazoles in rat and dog, in collaboration with Pfizer Limited, Sandwich.
7. Molecular studies of the fidelity of DNA repair, in collaboration with Shell Toxicology Laboratory, Sittingbourne.

Applicants must have, or expect to obtain, first or upper second class honours in Biochemistry or a related subject. Applications, stating the topics of interest and enclosing a curriculum vitae and the names and addresses of two referees should be sent without delay to:

Senior Academic Administrator,  
Department of Biochemistry,  
University of Surrey,  
Guildford,  
Surrey GU2 5XH. 2112(F)

U.M.I.S.T.  
University of Manchester  
Institute of Science  
and Technology  
Ph.D. RESEARCH IN  
FIBRE PHYSICS

Studentships are available for research in the following areas:

1. Micromechanisms involved in the texturing of synthetic fibres (S.R.S./C.A.S.E. Studentship with I.C.I. Fibres).

2. Thermomechanical response of synthetic fibres (S.R.S./C.A.S.E. Studentship with the Cotton Silk and Man-Made Fibres Research Association).

3. Fracture mechanism in oriental polymers: fibres and films (industrially sponsored).

Applicants should hold or expect to obtain a good honours degree in physics, materials science, engineering or a related subject, and should apply as soon as possible to Dr C. P. Buckley, Department of Textile Technology, UMIST, Manchester M60 1QD, from whom further details may be obtained. 2125(F)

UNIVERSITY OF  
NOTTINGHAM  
DEPARTMENT OF BOTANY  
S.R.C. C.A.S.E.

RESEARCH STUDENTSHIP

Applications are invited from persons holding or expecting to receive a First or Upper Second Class Honours Degree in Botany or in any of the Biological Sciences for a C.A.S.E. Studentship in collaboration with Asner Seeds Limited of Leicester to work on the somatic hybridisation of Pelargoniums using protoplasts.

Applications with the names and addresses of two referees and a curriculum vitae should be sent to Dr J. B. Power, Department of Botany, University of Nottingham, Nottingham. 2093(F)

UNIVERSITY OF GLASGOW  
DEPARTMENTS OF PATHOLOGY  
AND BIOCHEMISTRY  
M.R.C.

PARTNERSHIP AWARD

Applications are invited from graduates with an upper second class honours degree for a 3-year research studentship involving the analysis of monoclonal antibodies to human thyroglobulin in normal and diseased tissue. The successful applicant will be expected to work in both the Royal Infirmary and the Biochemistry Department at the University. Applications should be made by July 31 to Dr A. M. Campbell, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 4385M. 2099(F)

UNIVERSITY OF GLASGOW  
DEPARTMENT OF BOTANY  
Applications are invited for an  
S.R.C. C.A.S.E.  
STUDENTSHIP

tenable for three years from October 1979 to work on the resistance of potato tuber tissue to *Phytophthora infestans*. The research will offer interesting and varied opportunities for candidates interested in both the fundamental aspects and practical applications of research into mechanisms of disease resistance. It is expected that three months of each year will be spent with the collaborating institute, the Scottish Plant Breeding Station.

Further details may be obtained from Dr D. D. Clarke, Botany Department, Glasgow University, Glasgow G12 8QQ, to whom applications should be sent, naming two referees, by June 23, 1979. 2101(F)

IMPERIAL COLLEGE  
COST AND ENERGY  
EVALUATION OF  
MINERAL EXTRACTION  
PROCESSES

A Science Research Council C.A.S.E. STUDENTSHIP is offered in association with the Department of Industry, Warren Spring Laboratory, for a study to develop a Methodology of Cost and Energy Evaluation of Mineral Extraction Processes. The methodology will be developed with particular reference to the extraction of alumina from indigenous U.K. resources of aluminiferous materials.

Candidates from any background will be considered, but the study would be of particular interest to those with experience in mineral technology, extraction metallurgy, chemical engineering or chemistry.

Applicants should have, or expect to obtain a 1st or upper 2nd class honours degree. Applicants should send details of their qualifications plus the names and addresses of two referees, to Professor R. N. Pryor, Head of Department, Department of Mineral Resources Engineering, Imperial College of Science and Technology, Prince Consort Road, London SW7 2BP. 2152(F)

LONDON SCHOOL OF  
HYGIENE AND TROPICAL  
MEDICINE  
(University of London)  
Keppel Street, WC1E 7HT  
SCIENCE

RESEARCH COUNCIL:  
C.A.S.E. STUDENTSHIP

Applications are invited from candidates who hold or expect to obtain this summer at least an upper second class honours degree in Biochemistry or another appropriate discipline for a Research Studentship, tenable at the School in conjunction with Glaxo Group Research Ltd for three years from October 1, 1979. The project will be supervised by Dr M. W. Stewart of the Immunology Unit, Department of Medical Biology, and Dr M. W. Elves of Glaxo; and will be concerned with the study of immunological mechanisms involved in antigen-antibody complex disease and the possible modulation of these mechanisms. Applications, consisting of curriculum vitae and naming two referees, should be sent to the Secretary (A1) at the School. 2153(F)

THAMES POLYTECHNIC  
SCHOOL OF  
BIOLOGICAL SCIENCES  
S.R.C. STUDENTSHIP

Applications are invited from holders, or those expected to obtain a good honours degree for a S.R.C. studentship. The project will either: (i) An investigation of the purification of proteins by desorption from mixed-function, non-specific adsorbents using biospecific ligands desorbing agents ("affinity-elution chromatography") and is suitable for biochemist or biologically-oriented chemist. (Supervisor: Dr R. J. Ye or (ii) an investigation into the degradation pathway of the herbicide 2,4-dichlorophenoxy acetic acid *Acinetobacter* sp. and the induction of the enzymes involved, and is suitable for a biochemist or chemist. Some experience of microbiology preferable. (Supervisor: Dr A. R. Smith).

Further particulars and form application may be obtained from Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6 to whom completed application should be returned by June 26, 1979. 2096(F)

**UNIVERSITY OF ABERDEEN**  
DEPARTMENT OF CHEMISTRY  
S.R.C. C.A.S.E.  
STUDENTSHIPS 1979

Applications are invited for three A.S.E. studentships, two in cooperation with Borax Holdings, Ltd., and one in cooperation with British Gas, work in the undernoted fields.

- (1) Spectroscopic (UV and visible) and electrochemical study of the interaction of sulphide ions with metal ions in molten sodium borate. (Drs. J. A. Duffy and M.D. Ingram)
- (2) The effect of borate fluxes on sintering and solid-melt equilibria in ceramic bodies, and the relation between thermal history, phase composition microstructure, strength and optical properties. Project would also suit applicants with materials science or mineralogical background. (Dr. F.P. Glasser)

For both projects, a period of two months a year will be spent in the Max Research Centre, Chessington, Surrey.

(3) Fundamental reactions relevant to methane combustion. (Dr. L. Bateman)

A period of two months a year will be spent at the London Research Station of the British Gas Corporation. Applicants holding or expecting to obtain a first or upper second class honours degree should communicate with the designated supervisor (Meston Smith, Old Aberdeen AB9 2UE). 2113(F)

**UNIVERSITY OF WARWICK**  
RESEARCH STUDENTSHIPS  
BIOLOGICAL SCIENCES

Research Studentships in Microbiology (1, 2 and 3) or Virology (4) leading to a Ph.D. are available in the Department of Biological Sciences as follows:—

- S.R.C./C.A.S.E.: "Methanotrophs: gums and polysaccharides and taxonomy" in conjunction with British Petroleum, Sunbury-on-Thames, under the supervision of Professor R. Whittenbury.
- S.R.C./C.A.S.E.: "The Production of Methanol by Micro-organisms" in conjunction with British Petroleum, Sunbury-on-Thames, under the supervision of Dr H. Dalton.
- N.E.R.C.: "The significance of methylobacteria in nitrification in the aquatic environment" under the supervision of Dr C. S. Dow.
- M.R.C./PARTNERSHIP: "The study of interspecies recombination in rotaviruses" in conjunction with Dr T. H. Flewett, East Birmingham Hospital, under the supervision of Dr M. A. McCrae.
- Applicants should write direct to Professor R. Whittenbury, Biological Sciences, University of Warwick, Coventry, CV4 7AL, giving a brief curriculum vitae and the names of two academic referees. 2073(F)

**UNIVERSITY OF BRADFORD**  
SCHOOL OF  
MEDICAL SCIENCES  
S.R.C. C.A.S.E.  
STUDENTSHIP

Applications are invited for a C.A.S.E. studentship tenable from October 1979 research on the adherence of oral bacteria related to their cell wall composition and conditions of growth. The project will involve biochemistry, molecular biology and genetics. The work will be carried out in collaboration with the Microbiology Division of the National Institute for Medical Research. Applicants should hold, or expect to obtain a First or Upper Second Class Honours Degree in Microbiology or Biochemistry, and the successful applicant will be required to enter for a higher degree. Further details of the research and application forms are available from Dr H. D. Hoghue, School of Medical Sciences, University of Bradford, BD7 1DP. To complete applications must be received asap. Ref. RS/MS/1/X. 2109(F)

**THE UNIVERSITY OF LEEDS**  
DEPARTMENT OF  
ORGANIC CHEMISTRY  
Research  
Studentships

Applications are invited for the following S.R.C./C.A.S.E. Studentships tenable in the Department of Organic Chemistry from October 1, 1979 in the following areas:

- (1) New  $\beta$ -lactam antibiotics
- (2) New cycloaddition reactions
- (3) Antiviral and antifungal agents

Applicants should hold, or expect to obtain, a First Class or Upper Second Class degree from U.K. universities (or C.N.A.A.) or Grad R.I.C. of equivalent standing. Further information and application forms are available from Professor P. G. Sammes, Department of Organic Chemistry, The University of Leeds, Leeds LS2 9JT. 2124(F)

**UNIVERSITY OF DURHAM**  
DEPARTMENT OF CHEMISTRY  
C.A.S.E. STUDENTSHIPS

Applications are invited for the following C.A.S.E. awards:

1. Spectroscopic Studies of Adsorbed Species and
2. A Neutron Scattering Study of Adsorbed Species: (Dr J. Howard and Professor T. C. Waddington)
3. E.S.C.A. Investigations of the Kinetics and Mechanism of the Weathering of Polymeric Materials and
4. Electron Spectroscopy: Investigations of Technologically Important Surfaces: (Professor D. T. Clark)
5. The Determination of Optical Constants of Liquids and Solutions in the Submillimetre Region: (Dr J. Yarwood)
6. Hydrocarbonylation Reactions for Alcohol Synthesis: (Dr M. Kilner)
7. Syntheses via Fluorinated Anions: (Professor R. D. Chambers).

Several of the above carry payments in addition to the normal S.R.C. rates for research studentships. The Chemistry Department is modern, research orientated, and possesses a very wide variety of physical and chemical techniques which are available to all research workers within the Department.

Applicants should hold, or expect to obtain a first or upper second class honours degree in chemistry (1→7), chemical physics (1→5) or physics (2→5). Further details may be obtained from the staff indicated, by writing to the Chemistry Department, University of Durham, South Road, Durham DH1 3LE. 2094(F)

**UNIVERSITY OF GLASGOW**  
DEPARTMENT OF  
BIOCHEMISTRY  
in cooperation with I.C.I.  
S.R.C. C.A.S.E.  
STUDENTSHIP

An award will be tenable from October 1, 1979 in support of research on the effects of Tamoxifen and other anti-oestrogens on uterine transcription.

Applicants who should possess or expect to obtain a First or Upper Second Class Honours degree in Biochemistry or a related subject should write to Dr J. T. Knowler, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ. 2100(F)

**UWIST**  
(University of Wales)

**S.R.C. C.A.S.E.  
STUDENTSHIP**
